# CRYPTOGRAPHY

---

Basics Of Cryptography

Diffie-Hellman Key Exchange

Elgamal Cryptosystem

Symmetric and Asymmetric Crypto

RSA Cryptosystem

# Cryptography

---

The study of techniques for secure communication in presence of eavesdroppers

## Key Terms:

- ▶ Plain Text
- ▶ Cipher Text
- ▶ Keys
  - ▶ Symmetric Key
  - ▶ Asymmetric Key
  - ▶ Public Key
  - ▶ Private Key

# Symmetric Key Cryptosystem

---

use the same cryptographic keys for both encryption of plaintext and decryption of cipher text

- ❑ Both the parties should have the access to same secret key
- ❑ Any third person, if obtains the key can decode the cipher text even without letting the communicators know that their key is exposed.
- ❑ Are exposed to various attacks such as known-plaintext attacks, chosen-plaintext attacks, differential cryptanalysis and linear cryptanalysis
- ❑ Eg. Caser Cipher, Vigenere Cipher, XOR Cipher

# Shift Cipher

- ▶ Based on Shift parameter ( $s$ )
- ▶ Method can be improved by randomly choosing distinct keys for distinct position.
- ▶ Eg. Caesar Cipher, Vigenere Cipher (Polyalphabetic Cipher) One Time Pad
- ▶ Random Numbers and Pseudorandom key generators are used to generate private key space.

## Reason for failure

- ▶ Easy to compute all possible cipher text with modern computational power.
- ▶ Frequency Fingerprint provides a backdoor for decrypting cipher text. Also certainty of presence of a message makes it easy to decrypt the cipher text.

use different cryptographic keys  
for encryption of plaintext and  
decryption of cipher text

# Asymmetric Key Cryptosystem

---

- ❑ Also called Public Key Cryptography
- ❑ Method uses both public key and private keys for encryption and decryption. Private keys are kept with individuals.
- ❑ Any person can encrypt the message by using public key of the receiver but decryption can be done only by private keys.
- ❑ Strength of such system lies on degree of difficulty to determine private keys from corresponding public keys.
- ❑ Eg. Diffie Hellman, Digital Signature algorithm, RSA, ElGamal etc;

# RSA Cryptosystem

---

- ❑ A practical public-key cryptosystem where the encryption key is public while the decryption key is kept secret.
- ❑ Described by Rivest, Shamir and Adleman in 1977.
- ❑ Algorithm requires to big prime numbers (over 250 digit) long and is secure as long as factorization remains a computationally expensive task with most modern available computers.
- ❑ Theoretical Quantum computers with exceptionally high computation power have proven to break RSA using the famous Shor's algorithm.

# The Algorithm

- ▶ Euler's Theorem  $a^{\phi(n)+1} \equiv a \pmod n$
- ▶ Euler totient function is multiplicative.  $\phi(n) = \phi(p_1) * \phi(p_2)$
- ▶ For prime  $p$ ,  $\phi(p) = p - 1$  where  $n = p_1 * p_2$
- ▶ Take two large prime numbers,  $p_1$  and  $p_2$ . Let  $n = p_1 * p_2$ , then  
 $\phi(n) = \phi(p_1) * \phi(p_2) = (p_1 - 1)(p_2 - 1)$
- ▶ Select base  $e$  such that  $1 < e < n$  and  $(e, n) = 1$ ;  $e, n$  are co-prime and a random int  $k$ .
  - ❖ Note that finding  $\phi(n)$  is very costly if primes  $p_1$  and  $p_2$  are very big unless we know  $p_1$  or  $p_2$  or both.
- ▶  $a^{k*\phi(n)+1} \equiv a \pmod n$  Find  $d = \frac{k*\phi(n)+1}{e} = \frac{k*(p_1-1)*(p_2-1)+1}{e} = \frac{k*(n-p_1-p_2+1)+1}{e}$

# The RSA Algorithm

1. Generate prime  $p_1, p_2$  and random base  $e$ .  $p_1$  and  $p_2$  are private keys.

2. Find  $n = p_1 * p_2$ . and share public keys  $e$  and  $n$ .

3. Calculates  $d = \frac{k * (p_1 - 1) * (p_2 - 1) + 1}{e}$ , and find  $m = g^d \text{ mod } n$  which gives him message  $m$ .

Rohan

$e, n$  is  
now  
public

1. Receives  $e, n$

Decrypting  
the  
message.

Encrypting  
the  
message.

$g$  is  
now  
public

2. Say he has encoded message  $m$ . Calculate  $g = m^e \text{ mod } n$  and send it back to Shyam.

# Key Generation

---

- ▶ Usually  $e$  is chosen small, where  $(e, n) = 1$
- ▶ Generating Big Prime Numbers  $p_1$  and  $p_2$ .  
Using Probabilistic Primality test,
  1. Rabin Miller Test
  2. Baillie-PSW primality test

Deterministic Primality Test like AKS can also be used but it's a bit computationally slower.

# Diffie-Hellman Key Exchange

Method to securely exchange private keys over a public channel

## Discrete Logarithm Problem

given prime  $p$ , and numbers  $a, g$  its computationally very costly to find  $k$  such that

$$g = a^k \pmod{p}$$

for large values of  $p$  (say 100 digits long)

- ▶ Earlier exchange of private keys involved some secure physical channel such as courier, paper etc.
- ▶ DH made it possible to securely exchange private keys between parties over the internet.
- ▶ Key Factor:
  - ▶ Computation Expense of discrete logarithm problem is very high for large primes.
  - ▶ Involves high communication overhead in case of sharing keys to multiple parties.

# Diffie-Hellman Key Exchange

Shyam

1. Generate prime  $p$  and random base  $a < p$
2. Generate Private key  $k_1$  and find  $g_1 = a^{k_1} \bmod p$
3. Share  $g_1, a, p$  publicly.
4. Receives  $g_2$  from Rohan.
5. Find  $g = g_2^{k_1} \bmod p$   
 $= a^{k_1 \cdot k_2} \bmod p$

Rohan

$g_1, a,$   
 $p$  is  
now  
public

$g_2$  is  
now  
public

1. Receives  $a, p, g_1$
2. Generate Private key  $k_2$  and find  $g_2 = a^{k_2} \bmod p$
3. Send  $g_2$  to Shyam publicly
4. Find  $g = g_1^{k_2} \bmod p$   
 $= a^{k_1 \cdot k_2} \bmod p$

Even if someone has  $a, p, g_1, g_2$  its currently impossible for them to get key  $g$ .  
Thanks to computational complexity of discrete logarithm problem!

# Discrete Logarithm Problem

---

Elgamal (1984): discrete logarithm problem (DLP).

- ▶ Group  $G$  is set with operation  $(\cdot)$  and each element has inverse.
- ▶ Main idea: very easy to compute  $h = g^x$  for given  $x$ , but very hard to find  $x$  given  $h$  and  $g$ .
- ▶ Popular choices: finite fields and elliptic curves.

# Problems Related to DLP

---

Given an abelian group  $(G, \cdot)$  and  $g \in G$  of order  $n$ .

- ▶ Discrete Logarithm Problem (DLP) : Given  $h \in G$  such that  $h = g^x$  find  $x$ .  $(\text{DLP}(g, h) \rightarrow x)$
- ▶ Computational Diffie-Hellman Problem (CDH) : Given  $a = g^x$  and  $b = g^y$  find  $c = g^{xy}$   $(\text{CDH}(g, a, b) \rightarrow c)$ .
- ▶ Decisional Diffie-Hellman Problem (DDH) : Given  $a = g^x$ ,  $b = g^y$  and  $c = g^z$ , determine if  $g^{xy} = g^z$  or equivalently  $xy \equiv z \pmod n$   
 $(\text{DDH}(g, a, b, c) \rightarrow \text{true/false})$

# Breaking the discrete logarithm problem

---

For example: In case of Elliptic Curves

$$Q = P^x$$

$$Q * P^{-am} = P^b$$

Baby-step, giant-step

- ▶ Calculate  $m = \lceil \sqrt{n} \rceil$
- ▶ For every  $b$  in  $0, \dots, m$ , calculate  $bP$  and store the results in a hash table.
- ▶ For every  $a$  in  $0, \dots, m$ :
  - ▶ calculate  $P^{am}$ ;
  - ▶ calculate  $Q * P^{-am}$ ;
  - ▶ check the hash table and look if there exist a point  $P^b$  such that  $Q * P^{-am} = P^b$ ;
  - ▶ if such point exists, then we have found  $x = am + b$ .
  - ▶ time and space complexity  $O(\sqrt{n})$  or  $O(2^{bk/2})$  {VERY LARGE TO BREAK}

# Discrete Logarithm Problem

---

- ▶ Let  $(G, *)$  be an abelian group.
- ▶ Discrete Logarithm Problem Given  $g, h \in G$ , find an  $x$  (if it exists) such that

$$g^x = h.$$

- ▶ The difficulty of this problem depends on the group  $G$ :
  - ▶ Very easy: polynomial time algorithm, e.g.  $(\mathbb{Z}_N, +)$
  - ▶ Hard: sub-exponential time algorithm, e.g.  $(\mathbb{F}_p, \times)$
  - ▶ Very hard: exponential time algorithm, e.g. elliptic curve groups.

# ElGamal Encryption - Key Generation

---

ElGamal (1985): A public key cryptosystem and a signature scheme based on discrete logarithms.

## Domain Parameter Generation:

- ▶ Generate a “large prime”  $p$  ( $\geq 1024$  bits) such that  $p-1$  is divisible by another “large prime”  $q$  ( $> 160$  bits).
- ▶ Compute a generator  $g$  of the multiplicative group of order  $q$  in  $GF(p)^*$ , via (for some random  $r$ )

$$g \equiv r^{(p-1)/q} \pmod{p}$$

until  $g \neq 1$ .

# ElGamal Encryption - Key Generation

---

Key Generation:

- ▶ Select a random integer  $a$ ,  $1 \leq a \leq q - 1$  and compute

$$h \equiv g^a \pmod{p}$$

- ▶ Public key =  $(p, g, h)$  which can be published.
- ▶ Private key =  $a$  which needs to be kept secret.

# ElGamal - Encryption / Decryption

---

Shyam encrypts a message for Rohan as follows:

- ▶ Obtain Rohan's authentic public key  $(p, g, h)$ .
- ▶ Generate random  $k$   
 $(1 < k < q - 1)$   
with  $\gcd(k, p - 1) = 1$
- ▶  $r \equiv g^k \pmod{p}$  ( $k$  and  $r$  are ephemeral key pair)
- ▶  $s \equiv h^k \cdot m \pmod{p}$  ( $0 \leq m \leq p - 1$ )
- ▶ Ciphertext:  $c = (r, s)$

To recover the message, Rohan does the following:

$$m \equiv s \cdot r^{-a} \pmod{p}$$

Indeed:

$$r^{-a} \equiv g^{-ka} \equiv h^{-k} \pmod{p}$$

# Questions & Discussion

---
