simultaneously update

w_j (for $j = 1, \dots, n$) and b

}

An alternative to gradient descent

→ Normal equation

- Only for linear regression
- Solve for w, b without iterations

Disadvantages

- Doesn't generalize to other learning algorithms.
- Slow when number of features is large ($> 10,000$)

What you need to know

- Normal equation method may be used in machine learning libraries that implement linear regression.
- Gradient descent is the recommended method for finding parameters w, b

Practical Tips for Linear Regression

Feature Scaling Part 1

Feature and parameter values

$$\widehat{price} = w_1 x_1 + w_2 x_2 + b$$

size # bedrooms

x_1 : size (feet²)
range: 300 – 2,000

x_2 : # bedrooms
range: 0 – 5

Small

one training example

size of the parameters w_1, w_2 ?

←

$$w_1 = 50, \quad w_2 = 0.1, \quad b = 50$$

$$\widehat{price} = \frac{50 * 2000}{100,000k} + \frac{0.1 * 5}{0.5k} + \frac{50}{50k}$$

$$\widehat{price} = \$100,050.5k = \$100,050,500$$

→

$$w_1 = 0.1, \quad w_2 = 50, \quad b = 50$$

small large

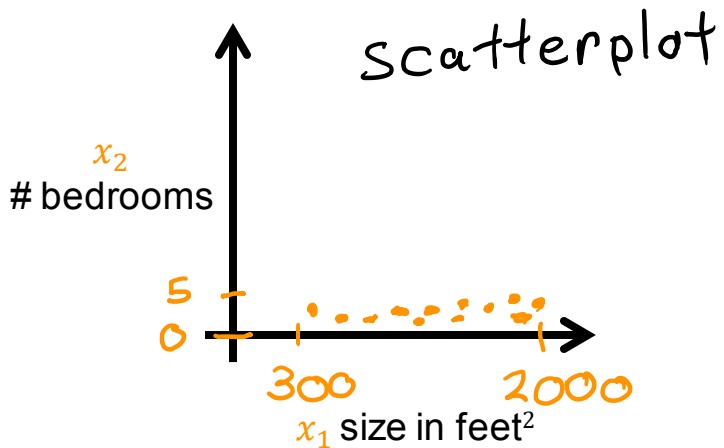

$$\widehat{price} = \frac{0.1 * 2000k}{200k} + \frac{50 * 5}{250k} + \frac{50}{50k}$$

Checking Gradient Descent for Convergence

Gradient descent

$$\left\{ \begin{array}{l} w_j = w_j - \alpha \frac{\partial}{\partial w_j} J(\vec{w}, b) \\ b = b - \alpha \frac{\partial}{\partial b} J(\vec{w}, b) \end{array} \right.$$

Make sure gradient descent is working correctly

objective: $\min_{\vec{w}, b} J(\vec{w}, b)$ $J(\vec{w}, b)$ should **decrease** after every iteration

Automatic convergence test

Let ϵ "epsilon" be 10^{-3} .
0.001

If $J(\vec{w}, b)$ decreases by $\leq \epsilon$ in one iteration, declare convergence.

(found parameters \vec{w}, b to get close to global minimum)

Practical Tips for Linear Regression

Choosing the Learning Rate

Identify problem with gradient descent

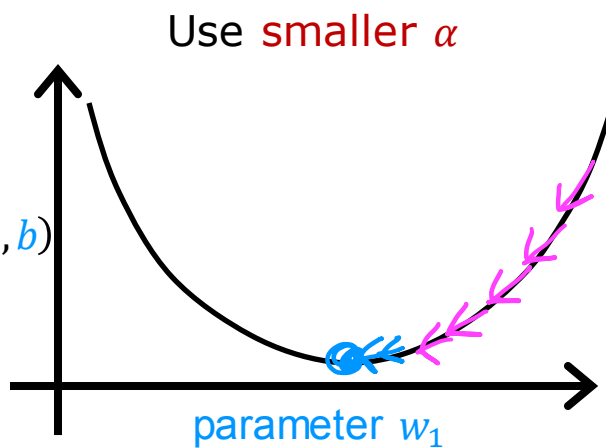

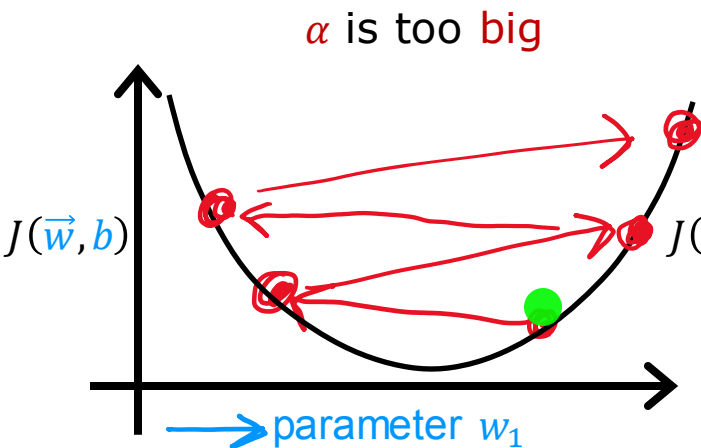

or learning rate is too large

$$w_1 = w_1 + \alpha d_1 \quad \uparrow \downarrow$$

use a minus sign

$$w_1 = w_1 - \alpha d_1 \quad \downarrow \uparrow$$

Adjust learning rate

With a small enough α , $J(\vec{w}, b)$ should **decrease** on every iteration

If α is too small, gradient descent takes a lot more iterations to **converge**

Values of α to try:

... 0.001 0.003 0.01 0.03 0.1 0.3 1 ...
 \nearrow \nearrow \nearrow \nearrow \nearrow
 $3\times$ $\approx 3\times$ $3\times$ $\approx 3\times$ $3\times$ $\approx 3\times$
