Polynomial factoring has famous practical algorithms over fields--finite, rational and $p$-adic. However, modulo prime powers, factoring gets harder because there is non-unique factorization and a combinatorial blowup ensues. For example, $x^2 + p$ mod $p^2$ is irreducible, but $x^2 + px$ mod $p^2$ has exponentially many factors in the input size (which here is logarithmic in $p$)! We present the first randomized poly(deg $f$, log $p$) time algorithm to factor a given univariate integral polynomial $f$ modulo $p^k$, for a prime $p$ and $k \leq 4$.

Thus, we solve the open question of factoring modulo $p^3$ posed in (Sircana, ISSAC'17).

Our method reduces the general problem of factoring $f$ mod $p^k$ to that of root finding of a related polynomial $E(y) \mod (p^k, \phi(x)^\ell)$ for some irreducible $\phi$ mod $p$. We can efficiently solve the latter for $k \leq 4$, by incrementally transforming $E$. Moreover, we discover an efficient refinement of Hensel lifting to lift factors of $f$ mod $p$ to those mod $p^4$ (if possible). This was previously unknown, as the case of repeated factors of $f$ mod $p$ forbids classical Hensel lifting.

1 A preliminary version of the paper was presented at the 44th International Symposium on Symbolic and Algebraic Computation (ISSAC), 2019 Dwivedi et al. (2019b). The current journal version includes new sections and algorithms for better exposition with relevant non-trivial examples to explain the algorithms. It also contains a complete proof for factoring $f$ mod $p^3$ which was left unproven in the conference version.

1. Introduction

Polynomial factorization is a fundamental question in mathematics and computing. In the last decades, quite efficient algorithms have been invented for various fields, e.g., over rationals (Lenstra et al., 1982), number fields (Landau, 1985), finite fields (Berlekamp, 1967; Cantor and Zassenhaus, 1981; Kedlaya and Umans, 2011) and \( p \)-adic fields (Chistov, 1987; Cantor and Gordon, 2000; Guàrdia et al., 2012). Being a problem of fundamental theoretical and practical importance, it has been very well studied; for more background refer to surveys, e.g., Kaltofen (1992); von zur Gathen and Panario (2001); Forbes and Shpilka (2015).

The same question over composite characteristic rings is believed to be computationally hard. For instance it is related to integer factoring (Shamir, 1993; Klivans, 1997). What is less understood is factorization over a local ring; especially, ones that are the residue class rings of \( \mathbb{Z} \) or \( \mathbb{F}_q[z] \). A natural variant is as follows.

**Problem.** Given a univariate integral polynomial \( f \) and a prime power \( p^k \), with \( p \) prime and \( k \in \mathbb{N} \); output a nontrivial factor of \( f \mod p^k \) in randomized \( \text{poly}(\deg f, k \log p) \) time.

Note that the polynomial ring \( (\mathbb{Z}/(p^k))[x] \) is not a unique factorization domain. So \( f \) may have a number of factorizations exponential in the input size (which in our setting is \( \deg(f) \log p \)). For example, \( x^2 + px \) has an irreducible factor \( x + \alpha p \mod p^2 \) for each \( \alpha \in [p] \) and so \( x^2 + px \) has exponentially many (wrt \( \log p \)) irreducible factors modulo \( p^2 \). This leads to a total breakdown in the classical factoring methods.

We give the first randomized polynomial time algorithm to non-trivial factor (or test for irreducibility) a polynomial \( f \mod p^k \), for \( k \leq 4 \).

Additionally, when \( f \mod p \) is a power of an irreducible, we provide (and count) all the lifts \( \mod p^k \) \((k \leq 4)\) of any factor of \( f \mod p \), in randomized polynomial time.

Usually, one factors \( f \mod p \) and tries to “lift” this factorization to higher powers of \( p \). If the former is a coprime factorization then Hensel lifting (Hensel, 1918) helps us in finding a non-trivial factorization of \( f \mod p^k \) for any \( k \). But, when \( f \mod p \) is a power of an irreducible then it is not known how to lift to some factorization of \( f \mod p^k \). To illustrate the difficulty let us see some examples (also see von zur Gathen and Hartlieb (1996)).

**Example 1 (coprime factor case).** Let \( f = x^2 + 10x + 21 \). Then \( f \equiv x(x + 1) \mod 3 \) and Hensel lemma lifts this factorization uniquely \( \mod 3^2 \) as \( f \equiv (x + 1 \cdot 3)(x + 1 + 2 \cdot 3) \equiv (x + 3)(x + 7) \mod 9 \). This lifting extends to any power of 3.

**Example 2 (power of an irreducible case).** Let \( f = x^3 + 12x^2 + 3x + 36 \) and we want to factor it \( \mod 3 \). Clearly, \( f \equiv x^3 \mod 3 \). By brute force one checks that, the factorization \( f \equiv x \cdot x^2 \mod 3 \) lifts to factorizations \( \mod 3^2 \) as: \((x^2 + 3x + 3), (x + 6)(x^2 + 6x + 3), (x + 3)(x^2 + 3)\). Only the last one lifts to \( \mod 3^3 \) as: \((x + 3)(x^2 + 9x + 3), (x + 12)(x^2 + 3), (x + 21)(x^2 + 18x + 3)\).

So the big issue is: efficiently determine which factorization, out of the exponentially many factorizations \( \mod p^j \), will lift to \( \mod p^{j+1} \)?

1.1. Previously known results

Using Hensel lemma it is easy to find a non-trivial factor of \( f \mod p^k \) when \( f \mod p \) has two coprime factors. So the hard case is when \( f \mod p \) is power of an irreducible polynomial. The first resolution in this case was achieved by von zur Gathen and Hartlieb (1998) assuming that \( k \) is “large”. They assumed \( k \) to be larger than the maximum power of \( p \) dividing the discriminant of the integral \( f \). Under this assumption (i.e. \( k \) is large), they showed that factorization modulo \( p^k \) is well behaved and it corresponds to the unique \( p \)-adic factorization of \( f \) (refer \( p \)-adic factoring Chistov (1987, 1994); Cantor and Gordon (2000); Guàrdia et al. (2012)). To show this, they used an extended version of
Hensel lifting (also discussed in Borevich and Shafarevich (1986)). Using this observation they could also describe all the factorizations modulo \( p^k \), in a compact data structure. The complexity of von zur Gathen and Hartlieb (1998) was improved by Cheng and Labahn (2001).

The related questions of root finding and root counting of \( f \mod p^k \) are also of classical interest, see Niven et al. (2013); Apostol (2013). Root counting has interesting applications in arithmetic algebraic-geometry, for instance to compute Igusa’s local zeta function of a univariate integral polynomial (Zuniga-Galindo, 2003; Denef and Hoornaert, 2001; Dwivedi and Saxena, 2020). To the best of our knowledge, the first randomized polynomial time root-finding algorithm can be deduced from Panayi’s PhD work Panayi (1995). A root-counting algorithm based on Panayi’s work is described in (Pauli and Roblot, 2001, Section 8). A recent result of (Berthomieu et al., 2013, Cor.4) explicitly resolves these problems (all root-finding and counting) in randomized polynomial time. Again, it describes all the roots modulo \( p^k \), in a compact data structure. Neiger et al. (2017) improved the time complexity of Berthomieu et al. (2013). Very recently, Kopp et al. (2019) also found a randomized poly-time algorithm which counts all the roots of \( f \mod p^k \).

Derandomizing root counting problem remained open until very recently. A partial derandomization of root counting algorithm has been obtained by Cheng et al. (2018) last year; which runs in deterministic poly-time when \( k = O(\log \log p) \). Finally, Dwivedi et al. (2019a) gave a deterministic \( \text{poly}(\deg(f), k \log p) \)-time algorithm for the problem, which also generalizes to count all the basic irreducible factors of \( f \mod p^k \); taking a step closer towards irreducibility testing of \( f \mod p^k \).

Going back to factoring \( f \mod p^k \), von zur Gathen and Hartlieb (1996) discusses the hurdles when \( k \) is small. The factors could be completely unrelated to the corresponding \( p \)-adic factorization, since an irreducible \( p \)-adic polynomial could be reducible \( \mod p^k \) when \( k \) is small. We give an example from von zur Gathen and Hartlieb (1996).

\textbf{Example 3.} Polynomial \( f = x^2 + 3^k \) is irreducible over \( \mathbb{Z}/(3^{k+1}) \) and so over \( 3 \)-adic field. But, it is reducible \( \mod 3^k \) as \( f = x^2 + 3 \mod 3^k \).

von zur Gathen and Hartlieb also pointed out that the distinct factorizations are completely different and not nicely related, unlike the case when \( k \) is large. An example taken from von zur Gathen and Hartlieb (1996) is,

\textbf{Example 4.} \( f = (x^2 + 243)(x^2 + 6) \) is an irreducible factorization over \( \mathbb{Z}/(3^6) \). There is another completely unrelated factorization \( f = (x + 351)(x + 135)(x^2 + 243x + 249) \mod 3^6 \).

Many researchers tried to solve special cases, especially when \( k \) is constant. The only successful factoring algorithm is by Sălăgean (2005) over \( \mathbb{Z}/(p^2) \); it is actually related to Eisenstein’s criterion for irreducible polynomials. The next case, to factor modulo \( p^3 \), is unsolved and was recently highlighted in Sircana (2017).

\textbf{1.2. Our results}

We saw that even after the attempts of last two decades we do not have an efficient algorithm for factoring \( \mod p^k \). Naturally, we would like to first understand the difficulty of the problem when \( k \) is constant. In this direction we make significant progress by devising a unified method which solves the problem when \( k = 2, 3 \) or 4 (and sketch the obstructions we face when \( k \geq 5 \)). Our first result is,

\textbf{Theorem 1.} Let \( p \) be prime, \( k \leq 4 \) and \( f \in \mathbb{Z}[x] \) be a univariate integral polynomial. Then, \( f \mod p^k \) can be factored (find a non-trivial factor or report irreducible) in randomized \( \text{poly}(\deg f, \log p) \) time.

\textbf{Remarks.} (1) The procedure to factor \( f \mod p^4 \) also factors \( \mod p^3 \) and \( \mod p^2 \) (and tests for irreducibility) in randomized \( \text{poly}(\deg f, \log p) \) time. This solves the open question of efficiently factoring \( f \mod p^4 \) (Sircana, 2017) and generalizes Sălăgean (2005).

(2) Our method can as well be used to factor a ‘univariate’ polynomial \( f \in (\mathbb{F}_p[z]/(\psi^k))[x] \), for \( k \leq 4 \) and irreducible \( \psi(z) \mod p \), in randomized \( \text{poly}(\deg f, \deg \psi, \log p) \) time.
Next, we do more than just factoring \( f \) modulo \( p^k \) for \( k \leq 4 \): Given that \( f \) is power of an irreducible mod \( p \) (hard case for Hensel lemma), we show that our method works in this case to give all the lifts \( g \) mod \( p^k \) (possibly exponentially many) of any given factor \( \tilde{g} \) of \( f \) mod \( p \), for \( k \leq 4 \).

**Theorem 2.** Let \( p \) be prime, \( k \leq 4 \) and \( f \in \mathbb{Z}[x] \) be a univariate integral polynomial such that \( f \) mod \( p \) is a power of an irreducible polynomial. Let \( \tilde{g} \) be a given factor of \( f \) mod \( p \). Then, in randomized \( \text{poly}(\deg f, \log p) \) time, we can compactly describe (and count) all possible factors of \( f \) mod \( p^k \) which are lifts of \( \tilde{g} \) (or report that there are none).

**Remark.** Theorem 2 can be seen as refinement of Hensel lifting method (Lemma 4) to \( \mathbb{Z}/(p^k) \), \( k \leq 4 \). To lift a factor \( f_1 \) of \( f \) mod \( p \), Hensel lemma relies on a cofactor \( f_2 \) which is coprime to \( f_1 \). Our method needs no such assumption and it directly lifts a factor \( \tilde{g} \) of \( f \) mod \( p \) to (possibly exponentially many) factors \( g \) mod \( p^k \).

### 1.3. Proof technique— root finding over local rings

Our proof involves two main techniques which may be of general interest.

**Technique 1:** Known factoring methods mod \( p \) work by first reducing the problem to that of root finding mod \( p \). In this work, we efficiently reduce the problem of factoring \( f \) modulo the principal ideal \( (p^k) \) to that of finding roots of some polynomial \( E(y) \in (\mathbb{Z}[x])[y] \) modulo a bi-generated ideal \( (p^k, \varphi^k) \), where \( \varphi \) is an irreducible factor of \( f \) mod \( p \). This technique works for all \( k \geq 1 \).

**Technique 2:** Next, we find a root of the equation \( E \equiv 0 \mod (p^k, \varphi^k) \), assuming \( k \leq 4 \). With the help of the special structure of \( E \) we will efficiently find all the roots \( y \) (possibly exponentially many) in the local ring \( \mathbb{Z}[x]/(p^k, \varphi^k) \).

It remains open whether this technique extends to \( k = 5 \) and beyond (even to find a single root of the equation). The possibility of future extensions of our technique is discussed in Section 5.

### 1.4. Proof overview

**Proof idea of Theorem 1.** Firstly, assume that the given degree \( d \) integral polynomial \( f \) satisfies \( f \equiv \varphi^e \mod p \) for some \( \varphi \in \mathbb{Z}[x] \) which is irreducible mod \( p \). Otherwise, using Hensel lemma (Lemma 4) we can efficiently factor \( f \) mod \( p^k \).

Any factor of such an \( f \) mod \( p^k \) must be of the form \((\varphi^a - py) \mod p^k \), for some \( 1 \leq a < e \) and \( y \in (\mathbb{Z}/(p^k))[x] \). In Theorem 11, we first reduce the problem of finding such a factor \((\varphi^a - py) \mod p^k \) to finding roots of some \( E(y) \in (\mathbb{Z}[x])[y] \) in the local ring \( \mathbb{Z}[x]/(p^k, \varphi^k) \). This is inspired by the \( p \)-adic power series expansion of the quotient \( f/(\varphi^a - py) \). On going mod \( p^k \) we get a polynomial in \( y \) of degree \( k - 1 \); which we want to be divisible by \( \varphi^k \).

The root \( y \) of \( E \) mod \((p^k, \varphi^k) \) can be further decomposed into coordinates \( y_0, y_1, \ldots, y_{k-1} \in \mathbb{F}_p[x]/(\varphi^k) \) such that \( y = y_0 + py_1 + \cdots + p^{k-1}y_{k-1} \mod (p^k, \varphi^k) \). When we take \( k = 4 \), it turns out that the root \( y \) only depends on the coordinates \( y_0 \) and \( y_1 \) (i.e. \( y_2, y_3 \) can be picked arbitrarily).

Next, we reduce the problem of root finding of \( E(y_0 + py_1) \) in the ring \( \mathbb{Z}[x]/(p^4, \varphi^4) \) to root finding in characteristic \( p \); of some \( E(y_0, y_1) \) in the ring \( \mathbb{F}_p[x]/(\varphi^4) \) (Lemma 14). We make use of a subroutine Root-Find given by Panayi (1995); Berthomieu et al. (2013) which can efficiently find all the roots of a univariate \( g(y) \) in the ring \( \mathbb{Z}/(p) \). In fact, we need a slightly generalized version of it, to find all the roots of a given \( g \) in the field \( \mathbb{F}_p[x]/(\varphi(x)) \) (Section 2.4).

Note that \( y_0, y_1 \) are in the ring \( \mathbb{F}_p[x]/(\varphi^4) \) and so they can be decomposed as \( y_0 = y_0 + \varphi y_{0,1} + \cdots + \varphi^{k-1} y_{0,4a-1} \) and \( y_1 = y_1 + \varphi y_{1,1} + \cdots + \varphi^{k-1} y_{1,4a-1} \), with all \( y_i,j \)'s in the field \( \mathbb{F}_p[x]/(\varphi) \).

To get \( E(y_0, y_1) \mod (p, \varphi^4) \) the idea is: first divide by \( p^2 \), and then to go modulo the ideal \((p, \varphi^4) \). Apply Algorithm Root-Find to solve \( E(y_0 + py_1)/p^2 \equiv 0 \mod (p, \varphi^4) \). This allows us to fix some part of \( y_0 \), say \( a_0 \in \mathbb{F}_p/(\varphi^4) \), and we can replace it by \( a_0 + \varphi^{4a_0} y_0 \). We then proceed as usual. Thus, \( p^3(E(a_0 + \varphi^{4a_0} y_0 + py_1) \mod (p^4, \varphi^4) \) and we divide out by this \( p^3 \) (and change the modulus to \((p, \varphi^4) \).}
Lemma 14 we show that when we go modulo the ideal \( \langle p, \varphi^{4a} \rangle \) to find \( a_0 \), we only need to solve a univariate polynomial equation in \( y_0 \) using Root-Find. So we only need to fix some part of \( y_0 \), that we called \( a_0 \), and \( y_1 \) is irrelevant. Finally, we get \( E'(y_0, y_1) \) such that \( E'(y_0, y_1) := E(a_0 + \varphi^0 y_0 + py_1)/p^3 \mod \langle p, \varphi^{4a} \rangle \). Importantly, the process yields at most two possibilities of \( E' \) (resp. \( a_0 \)) to deal with.

Lemma 14 also shows that the bivariate \( E'(y_0, y_1) \) is a special one of the form \( E'(y_0, y_1) \equiv E_1(y_0) + E_2(y_0)y_1 \mod \langle p, \varphi^{4a} \rangle \), where \( E_1 \in \langle \mathbb{F}_p[x]/(\varphi^{4a}) \rangle[y_0] \) is a cubic univariate polynomial and \( E_2 \in \langle \mathbb{F}_p[x]/(\varphi^{4a}) \rangle[y_0] \) is a linear univariate polynomial. We exploit this special structure to represent \( y_1 \) as a rational function of \( y_0 \), i.e., \( y_1 \equiv -E_1(y_0)/E_2(y_0) \mod \langle p, \varphi^{4a} \rangle \). The important issue is that we can calculate \( y_1 \) only when, on some specialization \( y_0 = a_0 \), the division by \( E_2(a_0) \) is well defined. So we guess each value of \( 0 \leq r \leq 4a \) and ensure that the valuation (with respect to the powers of \( \varphi \)) of \( E_1(y_0) \) is at least \( r \) but that of \( E_2(y_0) \) is exactly \( r \). Once we find such a \( y_0 \), we can efficiently compute \( y_1 \) as \( y_1 \equiv -(E_1(y_0)/\varphi^r)/(E_2(y_0)/\varphi^r) \mod \langle p, \varphi^{4a-r} \rangle \).

To find \( y_0 \), we find common solution of two equations: \( E_1(y_0) \equiv E_2(y_0) \equiv 0 \mod \langle p, \varphi^r \rangle \), for each guessed value \( r \), using Algorithm Root-Find. Since the polynomial \( E_2(y_0) \) is linear, it is easy for us to filter all \( y_0 \)'s for which valuation of \( E_2(y_0) \) is exactly \( r \) (Lemma 16). Thus, we could efficiently find all \( (y_0, y_1) \) pairs that satisfy the equation \( E'(y_0, y_1) \equiv 0 \mod \langle p, \varphi^{4a} \rangle \).

**Proof idea of Theorem 2.** If \( f \equiv \varphi^r \mod p \) then any lift \( g \) of a factor \( \tilde{g}(x) \equiv \varphi^0 \mod p \) of \( f \mod p \) will be of the form \( g \equiv (\varphi^a - py) \mod p^k \). So basically we want to find all the \( y \)'s mod \( p^{k+1} \) that appear in the proof idea of Theorem 1 above. This can be done easily, because Algorithm Root-Find (Section 2.4) Panay (1995): Berthomieu et al. (2013) describes all possible \( y_0 \)'s in a compact data structure. Moreover, using this, a count of all \( y \)'s can be provided as well.

2. Preliminaries

2.1. Factoring and lifting

The following theorem by Cantor-Zassenhaus (Cantor and Zassenhaus, 1981) efficiently finds all the roots of a given univariate polynomial over a finite field.

**Theorem 3 (Cantor-Zassenhaus).** Given a univariate degree \( d \) polynomial \( f \) over a given finite field \( \mathbb{F}_q \), we can find all the irreducible factors of \( f \) in \( \mathbb{F}_q[x] \) in randomized poly\((d, \log q)\) time.

Currently, it is a big open question to derandomize the preceding theorem. The known deterministic algorithms are ‘inefficient’ for example, the well known Berlekamp’s algorithm (Berlekamp (1967)) takes time \( \tilde{O}(p \cdot (dn)^{\omega}) \) where \( q = p^k \) for \( p \) prime and \( \omega \) is matrix-multiplication exponent.

Below we state a lemma, originally due to Hensel (Hensel, 1918), for \( \mathcal{I} \)-adic lifting of coprime factorization for a given univariate polynomial. Over the years, it has acquired many forms in different texts; the version being presented here is due to Zassenhaus (Zassenhaus, 1969).

**Lemma 4 (Hensel’s lemma and lift Hensel (1918)).** Let \( R \) be a commutative ring with unity, and let \( \mathcal{I} \subseteq R \) be an ideal. Given a polynomial \( f \in R[x] \), let \( g, h, u, v \in R[x] \) be polynomials, such that, \( f = gh \mod \mathcal{I} \) and \( gu + hv = 1 \mod \mathcal{I} \).

Then, for any \( \ell \in \mathbb{N} \), we can efficiently compute \( g^\ell, h^\ell, u^\ell, v^\ell \in R[x] \) such that

\[
  f = g^\ell h^\ell \mod \mathcal{I}^\ell \quad \text{(called lift of the factorization)}
\]

where \( g^\ell = g \mod \mathcal{I}, h^\ell = h \mod \mathcal{I} \) and \( g^\ell u^\ell + h^\ell v^\ell = 1 \mod \mathcal{I}^\ell \).

Moreover, \( g^\ell \) and \( h^\ell \) are unique up to multiplication by a unit.

2.2. A bit of commutative algebra

In this subsection we present some basic results in commutative algebra which will be helpful in Section 4.
Zero-Divisors. Let $R[x]$ be the ring of polynomials over $R = \mathbb{Z}/(p^k)$. The following lemma about zero divisors in $R[x]$ will be helpful.

**Lemma 5.** A polynomial $f \in R[x]$ is a zero divisor iff $f \equiv 0 \mod p$. Consequently, for any polynomials $f, g_1, g_2 \in R[x]$ and $f \not\equiv 0 \mod p$, $fg_1 = fg_2$ implies $g_1 = g_2$.

**Proof.** If $f \equiv 0 \mod p$ then $f \cdot p^{k-1}$ is zero, and $f$ is a zero divisor.

For the other direction, let $f \not\equiv 0 \mod p$ and assume $fg = 0$ for some non-zero $g \in R[x]$. Let

- $i$ be the biggest integer such that the coefficient of $x^i$ in $f$ is non-zero modulo $p$.
- $j$ be the biggest integer such that the coefficient of $x^j$ in $g$ has minimum valuation with respect to $p$.

Then, the coefficient of $x^{i+j}$ in $f \cdot g$ has same valuation as the coefficient of $x^j$ in $g$, implying that the coefficient is non-zero. This contradicts the assumption $f \cdot g = 0$.

The consequence follows because $f \not\equiv 0 \mod p$ implies that $f$ cannot be a zero divisor. □

**Quotient ideals.** We define the quotient ideal (analogous to division of integers) and look at some of its properties.

**Definition 6 (Quotient ideal).** Given two ideals $I$ and $J$ of a commutative ring $R$, we define the quotient of $I$ by $J$ as,

$$I : J := \{ a \in R \mid aJ \subseteq I \}.$$ 

It can be easily verified that $I : J$ is an ideal. Moreover, we can make the following observations about quotient ideals.

**Claim 7 (Cancellation).** Suppose $I$ is an ideal of ring $R$ and $a, b, c$ are three elements in $R$. By definition of quotient ideals, $ca \equiv cb \mod I$ iff $a \equiv b \mod I : \langle c \rangle$.

**Claim 8.** Let $p$ be a prime and $\varphi \in (\mathbb{Z}/(p^k))[x]$ be such that $\varphi \not\equiv 0 \mod p$. Given an ideal $I := \langle p^\ell, \varphi^m \rangle$ of $\mathbb{Z}[x]$.

1. $I : \langle p^i \rangle = \langle p^{\ell-i}, \varphi^m \rangle$, for $i \leq \ell$, and
2. $I : \langle \varphi^j \rangle = \langle p^\ell, \varphi^{m-j} \rangle$, for $j \leq m$.

**Proof.** We will only prove part (1), as the proof of part (2) is similar. If $c \in \langle p^{\ell-i}, \varphi^m \rangle$ then there exists $c_1, c_2 \in \mathbb{Z}[x]$, such that, $c = c_1 p^{\ell-i} + c_2 \varphi^m$. Multiplying by $p^i$,

$$p^i c = c_1 p^{\ell + i} + c_2 p^i \varphi^m \in I \Rightarrow c \in I : \langle p^i \rangle.$$ 

To prove the reverse direction, if $c \in I : \langle p^i \rangle$ then there exists $c_1, c_2 \in \mathbb{Z}[x]$, such that, $p^{i} c = c_1 p^{\ell} + c_2 \varphi^m$. Since $i \leq \ell$ and $p \nmid \varphi$, we know $p \mid c_2$. So, $c = c_1 p^{\ell-i} + (c_2/p) \varphi^m \Rightarrow c \in \langle p^{\ell-i}, \varphi^m \rangle$. □

**Lemma 9 (Compute quotient).** Given a polynomial $\varphi \in \mathbb{Z}[x]$ not divisible by $p$, define $I$ to be the ideal $\langle p^\ell, \varphi^m \rangle$ of $\mathbb{Z}[x]$. If $g(y) \in (\mathbb{Z}[x])[y]$ is a polynomial such that $g \equiv 0 \mod \langle p, \varphi^m \rangle$, then $p \mid g$ mod $I$ and $g/p$ mod $I : \langle p \rangle$ is efficiently computable.

**Proof.** The equation $g \equiv 0 \mod \langle p, \varphi^m \rangle$ implies $g = pc_1 + \varphi^m c_2$ for some polynomials $c_1, c_2 \in \mathbb{Z}[x][y]$. Going modulo $I$, $g \equiv pc_1$ mod $I$. Hence, $p \mid g$ mod $I$ and $g/p \equiv c_1$ mod $I : \langle p \rangle$ (Claim 7).

If we write $g$ in the reduced form modulo $I$, then the polynomial $g/p$ can be obtained by dividing each coefficient of $g$ mod $I$ by $p$. □
2.3. Representatives and representative roots

Let \( R \) be a commutative ring with addition + and multiplication \( \cdot \) and let \( S \) be a non-empty subset of \( R \). The product of the set \( S \) with a scalar \( a \in R \) is defined as \( aS := \{as | s \in S\} \). Similarly, the sum of a scalar \( u \in R \) with the set \( S \) is defined as \( u + S := \{u + s | s \in S\} \). Note that the product and the sum operations used inside the set are borrowed from the underlying ring \( R \). Also note that if \( S \) is the empty set then so are \( aS \) and \( u + S \) for any \( a, u \in R \).

Representatives. The symbol ‘*’ in a ring \( R \), wherever it appears, denotes any possible choice of an arbitrary element of \( R \). For example, suppose \( R = \mathbb{Z}/(p^k) \) for a prime \( p \) and a positive integer \( k \). In this ring, we will use the notation \( y = y_0 + py_1 + \cdots + p^i y_i + p^{i+1} \), where \( i + 1 < k \) and each \( y_j \in R/(p) \), to denote a set \( S_y \subseteq R \) such that

\[
y = \{y_0 + \cdots + p^i y_i + p^{i+1} y_{i+1} + \cdots + p^{k-1} y_{k-1} | \forall y_{i+1}, \ldots, y_{k-1} \in R/(p)\}.
\]

Notice that the number of distinct elements in \( R \) represented by \( y \) is \(|S_y| = p^{k-i-1}\).

We will sometimes write the set \( y = y_0 + py_1 + \cdots + p^i y_i + p^{i+1} \) succinctly as \( y = v + p^{i+1} \), where \( v \in R \) stands for \( v = y_0 + py_1 + \cdots + p^i y_i \).

In the following sections, we will add and multiply the set \(*\) with scalars from the ring \( R \). Let us define these operations as follows (* is treated as an unknown)

- \( u + \{\ast\} := \{u + \ast\} \) and \( u\{\ast\} := \{u\ast\} \), where \( u \in R \).
- \( c + [a + b\ast] = [(c + a) + b\ast] \) and \( c[a + b\ast] = [ac + bc\ast] \), where \( a, b, c \in R \).

Another important example of the * notation: Let \( R_0 = \mathbb{F}_p[x]/\langle\varphi(x)^k\rangle \) for a prime \( p \) and an irreducible \( \varphi \) mod \( p \). In this ring, we use the notation \( y = y_0 + \varphi y_1 + \cdots + \varphi^i y_i + \varphi^{i+1} \), where \( i + 1 < k \) and each \( y_j \in R_0/(\varphi) \), to denote a set \( S_y \subseteq R_0 \) such that

\[
y = \{y_0 + \cdots + \varphi^i y_i + \varphi^{i+1} y_{i+1} + \cdots + \varphi^{k-1} y_{k-1} | \forall y_{i+1}, \ldots, y_{k-1} \in R_0/(\varphi)\}.
\]

Representative roots. Let \( R_0 = \mathbb{F}_p[x]/\langle\varphi(x)^k\rangle \) for a prime \( p \) and an irreducible \( \varphi \) mod \( p \). Any element in \( R_0 \) can be written uniquely as \( y = y_0 + \varphi y_1 + \cdots + \varphi^{k-1} y_{k-1} \), where each \( y_j \) is in the field \( R_0/(\varphi) \).

Let \( g(y) \) be a polynomial in \( R_0[y] \), then a set \( y = y_0 + \varphi y_1 + \cdots + \varphi^i y_i + \varphi^{i+1} \) will be called a representative root of \( g \) iff

- All elements in \( y = y_0 + \varphi y_1 + \cdots + \varphi^i y_i + \varphi^{i+1} \) are roots of \( g \) and,
- Not all elements in \( y' = y_0 + \varphi y_1 + \cdots + \varphi^{i+1} y_{i+1} + \varphi^{i+1} \) are roots of \( g \).

We will sometimes represent the set of roots, \( y = y_0 + \varphi y_1 + \cdots + \varphi^i y_i + \varphi^{i+1} \), succinctly as \( y = v + \varphi^{i+1} \), where \( v \in R_0 \) stands for \( y = y_0 + \varphi y_1 + \cdots + \varphi^i y_i \). Such a pair, \((v, i + 1)\), will be called a representative pair.

The significance of defining representative roots will be clear in Section 2.4.

2.4. Root finding modulo \( \varphi(x)^i \)

Let us denote the ring \( \mathbb{F}_p[x]/\langle\varphi(x)^i\rangle \) by \( R_0 \) (for an irreducible \( \varphi(x) \) mod \( p \)). In this section, we give an algorithm to find all the roots \( y \in R_0 \) of a polynomial \( g \in R_0[y] \). To the best of our knowledge, the algorithm to find roots modulo \( p^i \) first appeared in Panayi’s PhD thesis Panayi (1995). Here, we adapt the algorithm by (Berthomieu et al., 2013, Cor.4) to find roots in \( R_0 \) in the form of representative roots. Recall the notation of * and representative roots from Section 2.3.

Note that \( R_0/(\varphi)^i = \mathbb{F}_p[x]/\langle\varphi(x)^i\rangle \), for \( j \leq i \), and \( R_0/(\varphi) = \mathbb{F}_q \) is the finite field of cardinality \( q := p^\deg(\varphi \mod p) \). A root \( y \) of \( g \) in \( R_0 \) has the following unique structure

\[
y = y_0 + \varphi y_1 + \varphi^2 y_2 + \cdots + \varphi^{i-1} y_{i-1},
\]
where each \( y_j \in \mathbb{F}_q \) for all \( j \in \{0, \ldots, i - 1\} \).

The output of this algorithm is simply a set of at most \( \text{deg} \, g \) many representative roots of \( g \). This bound of \( \text{deg} \, g \) is a curious by-product of the algorithm (Berthomieu et al., 2013, Cor.4).

Algorithm 1 Root-finding in ring \( R_0 \).

1: procedure Root-find\((g(y), \varphi^i)\)
2: \( \text{if} \ g(y) \equiv 0 \text{ in } R_0/\langle \varphi^i \rangle \text{ return } * \) (every element is a root).
3: \( \text{let } g(y) \equiv \varphi^a \tilde{g}(y) \text{ in } R_0/\langle \varphi^i \rangle, \) for the unique integer \( 0 \leq a < i \) and the polynomial \( \tilde{g}(y) \in R_0/\langle \varphi^{i-a} \rangle[y], \text{ s.t., } \tilde{g}(y) \not\equiv 0 \text{ in } R_0/\langle \varphi \rangle \) and \( \text{deg}(\tilde{g}) \leq \text{deg}(g) \).
4: Using Cantor-Zassenhaus algorithm (Theorem 3) find all the roots of \( \tilde{g}(y) \text{ in } R_0/\langle \varphi \rangle \).
5: \( \text{if} \ \tilde{g}(y) \text{ has no root in } R_0/\langle \varphi \rangle \text{ then return } \{\}. \) (Dead-end)
6: Initialize \( S = \{\}. \)
7: for each root \( a \) of \( \tilde{g}(y) \text{ in } R_0/\langle \varphi \rangle \) do
8: \( \text{Define } g_a(y) := \tilde{g}(a + \varphi y). \)
9: \( S' \leftarrow \text{Root-find}(g_a(y), \varphi^{i-a}). \)
10: \( S \leftarrow S' \cup (a + \varphi S'). \)
11: end for
12: return \( S \).
13: end procedure

Note that in Step 9 we ensure: \( \varphi | g_a(y) \). So, in every other recursive call to Root-find the second argument reduces by at least one. The key reason why \( |S| \leq \text{deg} \, g \) holds: The number of representative roots of \( g_a \) are upper bounded by the multiplicity of the root \( a \) of \( \tilde{g} \).

The implication of Algorithm 1 is summed up in the following theorem due to Panayi (1995); Berthomieu et al. (2013).

Theorem 10. (Panayi, 1995; Berthomieu et al., 2013, Cor.4) Given a bivariate \( g \in R_0[y] \) where \( R_0 = \mathbb{Z}[x]/\langle p, \varphi^i \rangle \), let \( Z \subseteq R_0 \) be the root set of \( g(y) \). Then \( Z \) can be expressed as the disjoint union of at most \( \text{deg}_y(g) \) many representative pairs \( (a_0, i_0) \) \( (a_0 \in R_0 \text{ and } i_0 \in \mathbb{N}) \).

These representative pairs can be found in randomized \( \text{poly}(\text{deg}_y(g), \log p, ak \text{ deg } \varphi) \) time.

Notice that this compact description of the root set \( Z \) allows us to calculate the size of \( Z \) too. Let us see how Algorithm 1 can be used to factor the polynomial given in Example 2. We adapt the Algorithm 1 here in the context \( R_0 = \mathbb{Z}/\langle p^k \rangle \).

Example 5. We have \( g(x) = x^3 + 12x^2 + 3x + 36 \) and \( p^k = 3^3 \). So \( g \equiv x^3 + 12x^2 + 3x + 9 \text{ mod } 27 \).

Using Theorem 3, the only root of \( \tilde{g}(x) := g \text{ mod } 3 \) is 0. So we shift \( g \) as \( g(0 + 3x) \equiv 9(x + 4) \text{ mod } 27 \).

Dividing by 9 both sides we have, \( g_a(x) \equiv x + 1 \text{ mod } 3 \) which has only root 2 modulo 3.

So we get exactly one representative root of \( g \text{ mod } 27: \ x = 0 + 3(2) + 3^2* \).

Putting 0, 1 and 2 in place of * we get the roots \(-21, -15 \) and \(-3 \) modulo 27. These correspond to degree one factors \((x + 21), (x + 12) \) and \((x + 3)\) of \( g \text{ mod } 27 \) as we saw in Example 2.

2.5. Input preprocessing and proof organization

We give some assumptions here, on the given input polynomial \( f \in \mathbb{Z}[x] \), which will be followed in further sections unless explicitly stated otherwise.

Preprocessing: Our task is to non-trivially factor a univariate integral polynomial \( f \in \mathbb{Z}[x] \) of degree \( d \) modulo a prime power \( p^k \). Without loss of generality, we can assume that \( f \not\equiv 0 \text{ mod } p \). Otherwise, we can efficiently divide \( f \) by the highest power of \( p \) possible, say \( p^l \), such that \( f(x) \equiv p^l \tilde{f}(x) \text{ mod } p^k \) and \( \tilde{f}(x) \not\equiv 0 \text{ mod } p \). In this case, it is equivalent to factor \( \tilde{f} \) instead of \( f \).

To simplify the input further, write \( f \text{ mod } p \) (uniquely) as a product of powers of coprime irreducible polynomials (Theorem 3). If there are two coprime factors of \( f \), using Hensel lemma,
for a polynomial \( \ell \) in \((\mathbb{Z}/(p^k))\)[x]. We have \( e \cdot \deg \varphi \leq \deg f \), for the integral polynomials \( f \) and \( \varphi \).

**Organization of paper:** Factoring a univariate modulo \( p \) goes through root finding in an extension field of \( \mathbb{F}_p \). Our factoring method passes through a similar stage. In Section 3, we reduce factoring \( f \mod p^k \) to root finding of \( E \in (\mathbb{Z}[x])[y] \) modulo the bi-generated ideal \( \langle p^k, \varphi a^k \rangle \) for some \( a < e \).

Section 4 proves our main Theorems 1 and 2. We show in Section 4.1 how to find (and count) roots of \( E \) in simpler case of \( k = 3 \). In rest of Section 4 we generalize the idea used for \( k = 3 \) to find (and count) roots of \( E \) for \( k = 4 \). In Section 5 we discuss the barriers for \( k = 5 \) and beyond in extending the idea for \( k = 4 \). Finally, we conclude in Section 6.

### 3. Factoring to root-finding

In this section we give a general framework to work on the problem of factoring \( f \mod p^k \) - we reduce factoring \( f \mod p^k \) to root finding in a more general ring. The reduction seems quite natural and we hope that factoring \( f \mod p^k \), for arbitrary \( k \) can be done efficiently within this framework.

Following the preprocessing in Section 2.5, it is enough to factor \( f \in \mathbb{Z}[x] \) such that

\[
 f \equiv \varphi^e + p\ell \mod p^k,
\]

where \( \varphi \in \mathbb{Z}[x] \) is an irreducible polynomial modulo \( p \). Up to multiplication by units, any non-trivial factor \( h \) of \( f \) has the form \( h \equiv \varphi^a - py \), as \( h \mod p \) is a factor of \( f \equiv \varphi^e \mod p \), where \( a < e \) and \( y \) is a polynomial in \((\mathbb{Z}/(p^k))[x] \).

Let us denote the ring \( \mathbb{Z}[x]/\langle p^k, \varphi a^k \rangle \) by \( R \). Also, denote the ring \( \mathbb{Z}[x]/\langle p, \varphi a^k \rangle \) by \( R_0 \). We define an auxiliary polynomial \( E \in R[y] \) via

\[
 E := f \cdot (\varphi^{a(k-1)} + \varphi^{a(k-2)}(py) + \ldots + \varphi^a(py)^{k-2} + (py)^{k-1}).
\]

Theorem 11 reduces the problem of factoring \( f \mod p^k \) to the problem of finding roots of the univariate polynomial \( E \) in ring \( R \). Thus, we convert the problem of finding factors of \( f \in \mathbb{Z}[x] \) modulo a principal ideal \( \langle p^k \rangle \) to root finding of a polynomial \( E \in (\mathbb{Z}[x])[y] \) modulo a bi-generated ideal \( \langle p^k, \varphi a^k \rangle \).

**Theorem 11 (Reduction theorem).** Given a prime power \( p^k \); let \( f, h \in \mathbb{Z}[x] \) satisfy \( f \equiv \varphi^e + p\ell \mod p^k \) and \( h \equiv \varphi^a - py \mod p^k \), with \( \ell, y \in (\mathbb{Z}/(p^k))[x] \) and \( a \leq e \). Then, \( h \) divides \( f \) modulo \( p^k \) if and only if

\[
 E = f \cdot (\varphi^{a(k-1)} + \varphi^{a(k-2)}(py) + \ldots + \varphi^a(py)^{k-2} + (py)^{k-1}) \equiv 0 \mod (p^k, \varphi a^k).
\]

**Proof.** Let \( Q \) denote the ring of fractions of the ring \((\mathbb{Z}/(p^k))[x] \). Since \( \varphi \) is not a zero divisor, \((E(y)/\varphi a^k) \in Q \).

We first prove the reverse direction. If \( E \equiv 0 \mod (p^k, \varphi a^k) \), then \( (E/\varphi a^k) \) is a polynomial over \((\mathbb{Z}/(p^k))[x] \). Multiplying \( h \) with \((E/\varphi a^k) \mod p^k \), we write,

\[
 (\varphi^a - py)((f/\varphi a^k) \Sigma_{k=0}^{k-1} \varphi^{a(k-1-i)}(py)^i) \equiv (f/\varphi a^k)(\varphi a^k - (py)^k) \equiv f \cdot \varphi a^k/\varphi a^k \equiv f \mod p^k.
\]

The first equality comes via geometric series. Hence, \( h \) divides \( f \) modulo \( p^k \).

For the forward direction, assume that there exists some \( g \in (\mathbb{Z}/(p^k))[x] \), such that, \( f(x) \equiv h(x)g(x) \mod p^k \). We get two factorizations of \( f \) in \( Q \),

\[
 f = h \cdot g \quad \text{and} \quad f = h \cdot (E/\varphi a^k).
\]

Subtracting the first equation from the second one,

\[
 h \cdot (g - (E/\varphi a^k)) = 0.
\]
Notice that \( h \) is not a zero divisor in \( \mathbb{Z}/(p^k)[x] \) (by Lemma 5) and is thus invertible in \( Q \). So, \( E/\varphi^{ak} = g \) in \( Q \). Since \( g \) is in \( (\mathbb{Z}/(p^k))[x] \), we deduce the equivalent divisibility statement: \( E(y) \equiv 0 \mod (p^k, \varphi^{ak}) \). □

Following the reduction in this section, we move on to find roots of \( E(y) \), when \( k \leq 4 \), in the next section (Sec. 4).

4. Main results: the Proof of Theorems 1 and 2

In this section we will prove Theorems 1 and 2. We want to find (and count) all the factors \( h \in (\mathbb{Z}/(p^k))[x] \) of the given degree \( d \) polynomial \( f \in \mathbb{Z}[x] \) modulo \( p^k \) for \( k \leq 4 \), where \( f \equiv \varphi^e + p \cdot \mod p^k \) and \( h = \varphi^a - py \) (Sec. 2.5).

We also recall the definitions from Section 3. We have \( R := \mathbb{Z}[x]/(p^k, \varphi^{ak}) \) and \( R_0 = \mathbb{Z}[x]/(p, \varphi^{ak}) \).

For a factor \( h \) of \( f \), define \( E \in \mathbb{R}[y] \) as
\[
E := f \cdot (\varphi^{a(k-1)} + \varphi^{a(k-2)} (py) + \cdots + \varphi^a (py)^{k-2} + (py)^{k-1}).
\]

The following two observations simplify our task of finding roots \( y \) of polynomial \( E(y) \).

1. First, due to symmetry, it is enough to find factors \( h \equiv \varphi^a \mod p \) with \( a \leq e/2 \). The assertion follows because \( f \equiv hg \mod p^k \) implies, at least one of the factors (say \( h \)) must be of the form \( \varphi^a \mod p \) for \( a \leq e/2 \). By Lemma 5, for a fixed \( h \equiv \varphi^a - py \mod p^k \), there is a unique \( g \equiv \varphi^{e-a} - py' \mod p^k \) such that \( f \equiv hg \mod p^k \). So, to find \( g \), it is enough to find \( h \).

2. Second, observe that any root \( y \in R \) (of \( E \in \mathbb{R}[y] \)) can be seen as \( y = y_0 + py_1 + p^2 y_2 + \cdots + p^{k-1} y_{k-1} \), where each \( y_i \in \mathbb{R} \) for all \( i \) in \( \{0, \ldots, k-1\} \). The following lemma decreases the required precision of a root \( y \).

**Lemma 12.** Let \( y = y_0 + py_1 + p^2 y_2 + \cdots + p^{k-1} y_{k-1} \) be a root of \( E \), where \( k \geq 2 \) and \( a \leq e/2 \). Then, all elements of the set \( y = y_0 + py_1 + p^2 y_2 + \cdots + p^{k-2} y_{k-3} + p^{k-2} y_{k-1} \) are also roots of \( E \).

**Proof.** Notice that the variable \( y \) is multiplied with \( p \) in \( E(y) \), implying \( y_{k-1} \) is irrelevant. A similar argument is applicable for the coefficient \( y_{k-2} \) in any term involving \( (py)^i \) for \( i \geq 2 \). The only surviving term containing \( y_{k-2} \) is \( f \varphi^{a(k-2)} (py) \). The coefficient of \( y_{k-2} \) in this term is \( \varphi^{a(k-2)} f p^{k-1} \), it also vanishes because \( \varphi^{a(k-2)} f \equiv \varphi^{a(k-2)} \varphi^e \equiv \varphi^{ak+e-2a} \equiv 0 \mod (p, \varphi^{ak}) \). □

**Root-finding modulo a principal ideal.** In next few sections we will see that finding roots of \( E \) in \( R \) goes through finding roots of intermediate polynomials in \( R_0 = \mathbb{F}_p[x]/(\varphi^{ak}) \) (i.e., modulo a principal ideal). Such an algorithm is described in Section 2.4, which is a slightly modified version of the theorem from (Berthomieu et al., 2013, Cor.4). It shows that all the roots of a polynomial \( g \in R_0[y] \) can be efficiently described.

4.1. Finding all the factors modulo \( p^k \) when \( k < 4 \)

In this section we partially prove Theorems 1 and 2, i.e., we efficiently find all the factors of \( f \mod p^2 \) and \( f \mod p^3 \). Although the case of \( k = 2 \) is already solved Sâlâgean (2005), the case of \( k = 3 \) was left open in Sircana (2017). The ideas in this section (for \( k \leq 3 \)) will be generalized to solve the case \( k = 4 \).

**Factoring \( f \mod p^2 \).** The reduction theorem (Theorem 11) and Lemma 12 make factoring mod \( p^2 \) easy: They imply that any root of \( E \) is independent of coordinates \( y_0 \) and \( y_1 \). So, either \( h = \varphi^a - py \) can not be a factor of \( f \mod p^2 \) or it is a factor for every value of \( y \in \mathbb{R} \). Substituting \( y = 0 \), we get that \( h \equiv \varphi^a - py \mod p^2 \) is a factor of \( f \) if and only if \( \varphi^a f \mod p^2 \). In fact, we get a simple irreducibility criteria— \( f \mod p^2 \) factors if and only if \( \varphi^a f \mod p^2 \) (first discovered by Sâlâgean (2005)).

**Factoring \( f \mod p^3 \).** Theorem 13 below solves the factoring problem modulo \( p^3 \).
Theorem 13. Given \( f \in \mathbb{Z}[x] \), a univariate polynomial of degree \( d \) and a prime \( p \in \mathbb{N} \), we give (and count) all the distinct factors of \( f \mod p^3 \) of degree at most \( d \) in randomized \( \text{poly}(d, \log p) \) time.

Note: We will assume that the leading coefficient of \( f \) is 1. Also, we will not distinguish two factors if they are same up to multiplication by a unit.

Proof of Theorem 13. By Theorem 3, a general \( f \) can be written as:

\[
 f(x) \equiv \prod_{i=1}^{n} f_i(x) \equiv \prod_{i=1}^{n} (\varphi_i^{e_i} + ph_i) \mod p^3,
\]  

(1)

where \( f_i(x) \equiv (\varphi_i^{e_i} + ph_i) \mod p^3 \) with \( \varphi_i \mod p^3 \) being monic and irreducible mod \( p \), \( e_i \in \mathbb{N} \), and \( h_i(x) \mod p^3 \) of degree \( < e_i \deg(\varphi_i) \), for all \( i \in [n] \).

Using Lemma 4, it is sufficient to consider the case \( f \equiv \varphi^e + ph \).

By Reduction theorem (Theorem 11) finding factors of the form \( \varphi^a - py \mod p^3 \) of \( f \equiv \varphi^e + ph \mod p^3 \), for \( a \leq e/2 \), is equivalent to finding all roots of the equation

\[
 E \equiv f \cdot (\varphi^{2a} + \varphi^a(py) + (py)^2) \equiv 0 \mod (p^3, \varphi^{3a}).
\]

Consider \( R := \mathbb{Z}[x] / (p^3, \varphi^{3a}) \) and \( R_0 := \mathbb{Z}[x] / (p, \varphi^{3a}) \) (analogous to Section 2).

Using Lemma 12, we know that all solutions of the equation \( E \equiv 0 \mod (p^3, \varphi^{3a}) \) will be of the form \( y = y_0 + p* \in R_0 \), for \( y_0 \in R_0 \). Substituting, we get

\[
 E \equiv ph\varphi^{2a} + (p^2h\varphi^a)y_0 + (p^2\varphi^e)y_0^2 \equiv 0 \mod (p^3, \varphi^{3a}).
\]

Looking at this equation mod \( (p^2, \varphi^{3a}) \), we get that \( h \equiv 0 \mod (p, \varphi^a) \) is a necessary condition for a root \( y_0 \) to exist. Define \( h := \varphi^ag_1 + pg_2 \) for unique \( g_1, g_2 \in \mathbb{F}_p[x] \), the equation becomes

\[
 E \equiv p^2g_2\varphi^{2a} + (p^2g_1\varphi^{2a})y_0 + (p^2\varphi^e)y_0^2 \equiv 0 \mod (p^3, \varphi^{3a}).
\]

This equation is already divisible by \( p^2 \) as well as \( \varphi^{2a} \). Using Claim 8, finding factors of the form \( \varphi^a - py \mod p^3 \) is equivalent to finding all roots of the equation

\[
 g_2 + g_1y_0 + \varphi^{e-2a}y_0^2 \equiv 0 \mod (p, \varphi^a).
\]

These roots can be obtained using one call to Root-FIND in randomized \( \text{poly}(d, \log p) \) time. Note that any root \( y_0 \) given by Root-FIND is an element of \( \mathbb{F}_p[x] / (\varphi^a) \), implying its degree in \( x \) is \( < a \deg(\varphi) \). This yields monic factors of \( f \mod p^3 \) (with \( 0 \leq a \leq e/2 \)).

For \( e > a > e/2 \), we can replace \( a \) by \( b := e - a \) in the above steps. Once we get a factor \( \varphi^b - py \mod p^3 \), we output the cofactor \( f / (\varphi^b - py) = (f / \varphi^{ak})(\varphi^{2a} + \varphi^a(py) + (py)^2) \) (which remains monic).

Since Theorem 10 gives the numbers of roots from Root-FIND, we also get a count on total number of factors in poly-time.

For a general \( f \) (Equation (1)), if \( N_i \) is the number of factors of \( f_i \mod p^3 \), then \( \prod_{i=1}^{n} N_i \) is the count on the number of distinct monic factors of \( f \mod p^3 \). \( \square \)

Let us illustrate the steps in the proof of Theorem 13 by an example.

Example 6. Let \( f = x^4 + 18x^3 + 33x^2 + 54x + 9 \) be an integral polynomial and pick \( p = 3, k = 3 \).

We need to find factors of \( f \equiv x^4 + 18x^3 + 6x^2 + 9 \mod 27 \); since \( f \equiv x^4 \mod 3 \), fix \( \varphi := x \in \mathbb{Z}[x] \). Say, we want to find quadratic factors of \( f \mod 27 \), so fix \( a = 2 \).

Recall the reduction theorem (Theorem 11), \( (\varphi^a - py) \) is a factor of \( f \mod p^3 \) iff

\[
 E := f \cdot (\varphi^{2a} + \varphi^a(py) + (py)^2) \equiv 0 \mod (p^3, \varphi^{3a}).
\]
\[ (x^4 + 18x^3 + 6x^2 + 9)(x^4 + x^2(3y_0) + 9y_0^2) \equiv 0 \pmod{27, x^6}. \quad (y = y_0 \text{ [Lemma 12]}) \]

\[ 9x^4y_0^2 + 18x^4y_0 + 9x^4 \equiv 0 \pmod{27, x^6}. \]

\[ y_0^2 + 2y_0 + 1 \equiv 0 \pmod{3, x^2}. \]

\[ (y_0 + 1)^2 \equiv 0 \pmod{3, x^2}. \]

Applying Panayi (1995); Berthomieu et al. (2013) (Theorem 10) on last equation, we get exactly one representative root \( y_0 = 2 + x^* \).

Choosing \( y_1 = 0 \) and \( y_0 = 2 + 0 \), we have a corresponding factor \((x^2 - 3(2 + 0)) \equiv (x^2 + 21) \pmod{27}\). The co-factor of this is \((x^2 + 18x + 12)\), giving

\[ f \equiv x^4 + 18x^3 + 6x^2 + 9 \equiv (x^2 + 21)(x^2 + 18x + 12) \pmod{27}. \]

**Remark.** Observe that the core idea for \( p^3 \) was to first reduce root finding of \( E \pmod{p^3, \psi^{3a}} \) to root finding modulo a principal ideal \( (p, \psi^a) \). It was then solved by just one application of Theorem 10. For \( p^3 \), we only needed to deal with a univariate polynomial in \( y_0 \).

The approach for \( k = 4 \) is similar, though it requires several applications of Theorem 10 to go to principal ideal \( (p, \psi^{4a}) \) (Sec. 4.2). Even after that, we are required to solve a bivariate equation modulo the principal ideal (as opposed to a univariate in the case \( k = 3 \)).

We will fix \( k = 4 \) for the rest of Section 4. The barriers for \( k > 4 \) will be discussed in Section 5.

### 4.2. Reduction to root-finding modulo a principal ideal of \( \mathbb{F}_p[x] \)

In this subsection, the task to find roots of \( E \) modulo the bi-generated ideal \( (p^4, \psi^{4a}) \) of \( \mathbb{Z}[x] \) will be reduced to finding roots modulo the principal ideal \( (\psi^{4a}) \) (of \( \mathbb{F}_p[x] \)).

Let us consider the equation \( E \equiv 0 \pmod{(p^4, \psi^{4a})} \). We have,

\[ f(\psi^{3a} + \psi^{2a}(py) + \psi^a(py)^2 + (py)^3) \equiv 0 \pmod{(p^4, \psi^{4a})}. \quad (2) \]

Using Lemma 12, we can assume \( y = y_0 + py_1 \),

\[ f(\psi^{3a} + \psi^{2a}p(y_0 + py_1) + \psi^a p^2(y_0^2 + 2py_0y_1) + (py_0)^3) \equiv 0 \pmod{(p^4, \psi^{4a})}. \quad (3) \]

The idea is to first solve this equation modulo \( (p^3, \psi^{4a}) \). Since \( f \equiv \psi^e \pmod{p, e \geq 2a} \), variable \( y_1 \) is redundant while solving this equation modulo \( p^3 \). The following lemma finds all representative pairs \((a_0, i_0)\) for \( y_0 \), such that \( E(a_0 + \psi^{i_0}y_0 + py_1) \equiv 0 \pmod{(p^3, \psi^{4a})} \) for all \( y_0, y_1 \in R \). Alternatively, we can state this in the polynomial ring \( R[y_0, y_1] \). Dividing by \( p^3 \), we will be left with an equation modulo the principal ideal \( (\psi^{4a}) \) (of \( \mathbb{F}_p[x] \)).

**Lemma 14 (Reduction to characteristic \( p \)).** We efficiently compute a unique set \( S_0 \) of all representative pairs \((a_0, i_0)\), where \( a_0 \in R_0 \) and \( i_0 \in \mathbb{N} \), such that,

\[ E((a_0 + \psi^{i_0}y_0) + py_1) = p^3 E'(y_0, y_1) \pmod{(p^4, \psi^{4a})} \]

for a polynomial \( E'(y_0, y_1) \in R_0[y_0, y_1] \) (depending on \((a_0, i_0)\)). Moreover,

1. \( |S_0| \leq 2 \) and, if our algorithm fails to find \( E' \), then Eqn. (3) has no solution.
2. \( E'(y_0, y_1) = E_1(y_0) + E_2(y_0)y_1 \), where \( E_1 \in R_0[y_0] \) is cubic in \( y_0 \) and \( E_2 \in R_0[y_0] \) is linear in \( y_0 \).
3. For every root \( y \in R \) of \( E \) there exists \((a_0, i_0) \in S_0 \) and \((a_1, a_2) \in R \times R \), such that \( y = (a_0 + \psi^{i_0}a_1) + pa_2 \) and \( E'(a_1, a_2) \equiv 0 \pmod{(p, \psi^{4a})} \).
We think of $E'$ as the quotient $E((a_0 + \phi^{i_0}y_0) + py_1)/p^3$ in the polynomial ring $R_0[y_0, y_1]$; and would work with it instead of $E$ in the root-finding algorithm.

**Proof.** Looking at Eqn. (3) modulo $p^2$,

$$f \phi^{2a}(\phi^a + py_0) \equiv 0 \mod (p^2, \phi^{4a}).$$

Substituting $f = \phi^e + ph_1$, we get $(\phi^e + ph_1)(\phi^{3a} + \phi^{2a}py_0) \equiv 0 \mod (p^2, \phi^{4a})$. Implying, $ph_1\phi^{3a} \equiv 0 \mod (p^2, \phi^{4a})$. Using Claim 8 the above equation implies that,

$$h_1 \equiv 0 \mod (p, \phi^a). \quad (4)$$

is a necessary condition for $y_0$ to exist.

We again look at Eqn. (3), but modulo $p^3$ now: $f(\phi^{3a} + \phi^{2a}py_0 + \phi^a p^2 y_0^2) \equiv 0 \mod (p^3, \phi^{4a})$.

Notice that $y_1$ is not present because of its coefficient: $p^2 f \phi^{2a} \equiv 0 \mod (p^3, \phi^{4a})$. Substituting $f = \phi^e + ph_1$, we get,

$$(\phi^e + ph_1)(\phi^{3a} + \phi^{2a}py_0 + \phi^a p^2 y_0^2) \equiv 0 \mod (p^3, \phi^{4a}).$$

Removing the coefficients of $y_0$ which vanish modulo $(p^3, \phi^{4a})$,

$$\phi^{e+a}p^2 y_0^2 + \phi^{3a} ph_1 + \phi^{2a} p^2 h_1 y_0 \equiv 0 \mod (p^3, \phi^{4a}).$$

From Eqn. (4), $h_1$ can be written as $ph_{1,1} + \phi^a h_{1,2}$, so

$$p^2 \left( \phi^{e+a} y_0^2 + \phi^{3a} h_{1,2} y_0 + \phi^a h_{1,1} \right) \equiv 0 \mod (p^3, \phi^{4a}).$$

We can divide by $p^2 \phi^{3a}$ using Claim 8 to get an equation modulo $\phi^a$ in the ring $\mathbb{F}_p[x]$. This is a quadratic equation in $y_0$. Using Theorem 10, we find the solution set $S_0$ with at most two representative pairs: for $(a_0, i_0) \in S_0$, every $y \in a_0 + \phi^{i_0} * + p *$ satisfies,

$$E \equiv 0 \mod (p^3, \phi^{4a}).$$

In other words, upon substituting $y = a_0 + \phi^{i_0}y_0 + py_1$ in $E(y)$, we get

$$E(a_0 + \phi^{i_0}y_0 + py_1) \equiv p^3 E'(y_0, y_1) \mod (p^4, \phi^{4a}),$$

for a “bivariate” polynomial $E'(y_0, y_1) \in R_0[y_0, y_1]$. This sets up the correspondence between the roots of $E$ and $E'$.

Substituting $(a_0 + \phi^{i_0}y_0 + py_1)$ in Eqn. (3), we notice that $E'(y_0, y_1)$ has the form $E_1(y_0) + E_2(y_0)y_1$ for a linear $E_2$ and a cubic $E_1$.

Finally, this reduction is constructive, because of Lemma 9 and Theorem 10, giving a randomized poly-time algorithm. □

### 4.3. Finding roots of a special bi-variate $E'(y_0, y_1)$ modulo $(p, \phi^{4a})$

The final obstacle is to find roots of $E'(y_0, y_1)$ modulo $(\phi^{4a})$ in $\mathbb{F}_p[x]$. The polynomial $E'(y_0, y_1) = E_1(y_0) + E_2(y_0)y_1$ is special because $E_2 \in R_0[y_0]$ is linear in $y_0$.

For a polynomial $u \in \mathbb{F}_p[x][y]$ we define valuation $\operatorname{val}_p(u)$ to be the largest $r$ such that $\phi^r | u$. Our strategy is to go over all possible valuations $0 \leq r \leq 4a$ and find $y_0$, such that,

- $E_1(y_0)$ has valuation at least $r$.
- $E_2(y_0)$ has valuation exactly $r$.

From these $y_0$’s, $y_1$ can be obtained by ‘dividing’ $E_1(y_0)$ by $E_2(y_0)$. The lemma below shows that this strategy captures all the solutions.
Lemma 15 (Bivariate solution). A pair \((u_0, u_1) \in R_0 \times R_0\) satisfies an equation of the form \(E_1(y_0) + E_2(y_0) y_1 \equiv 0 \mod (p, \varphi^a)\) if and only if \(\text{val}_{\varphi}(E_1(u_0)) \geq \text{val}_{\varphi}(E_2(u_0))\).

Proof. Let \(r\) be \(\text{val}_{\varphi}(E_2(u_0))\), where \(r\) is in the set \(\{0, 1, \ldots, 4a\}\). If \(\text{val}_{\varphi}(E_1(u_0)) \geq \text{val}_{\varphi}(E_2(u_0))\) then set \(u_1 \equiv -(E_1(u_0)/\varphi^r)/(E_2(u_0)/\varphi^r) \mod (p, \varphi^a-r)\). The pair \((u_0, u_1)\) satisfies the required equation.

(Note: If \(r = 4a\) then we take \(u_1 = \ast\).)

Conversely, if \(r' := \text{val}_{\varphi}(E_1(u_0)) - \text{val}_{\varphi}(E_2(u_0)) \leq 4a\) then, for every \(u_1\),
\[
\text{val}_{\varphi}(E_1(u_0)) + E_2(u_0)u_1 \equiv r' \Rightarrow E_1(u_0) + E_2(u_0)u_1 \equiv 0 \mod (p, \varphi^a).
\]

We can efficiently find all representative pairs for \(y_0\), at most three, such that \(E_1(y_0)\) has valuation at least \(r\) (using Theorem 10). The next lemma shows that we can efficiently filter all \(y_0\)'s, from these representative pairs, that give valuation exactly \(r\) for \(E_2(y_0)\).

Lemma 16 (Reduce to a unit \(E_2\)). Given a linear polynomial \(E_2(y_0) \in R_0[y_0]\) and an \(r \in \{4a - 1\}\), let \((b, i)\) be a representative pair modulo \((p, \varphi^r)\), i.e., \(E_2(b + \varphi^i y_0) \equiv 0 \mod (p, \varphi^r)\). Consider the quotient \(E_2'(y_0) := E_2(b + \varphi^i y_0)/\varphi^r\).

If \(E_2'(y_0)\) does not vanish identically modulo \((p, \varphi)\), then there exists at most one \(\theta \in R_0/(\varphi)\) such that \(E_2'\) vanishes identically modulo \((p, \varphi)\), and this \(\theta\) can be efficiently computed.

Proof. Suppose \(E_2(b + \varphi^i y_0) \equiv u + v y_0 \equiv 0 \mod (p, \varphi^r)\). Since \(y_0\) is formal, we get \(\text{val}_{\varphi}(u) \geq r\) and \(\text{val}_{\varphi}(v) \geq r\). We consider the three cases (with respect to these valuations),

1. \(\text{val}_{\varphi}(u) \geq r\) and \(\text{val}_{\varphi}(v) = r\): \(E_2'(\theta) \equiv 0 \mod (p, \varphi)\) except \(\theta = (-u/\varphi^r)/(v/\varphi^r) \mod (p, \varphi)\).
2. \(\text{val}_{\varphi}(u) = r\) and \(\text{val}_{\varphi}(v) > r\): \(E_2'(\theta) \equiv 0 \mod (p, \varphi)\) for all \(\theta \in R_0/(\varphi)\).
3. \(\text{val}_{\varphi}(u) > r\) and \(\text{val}_{\varphi}(v) > r\): \(E_2'(y_0)\) vanishes identically modulo \((p, \varphi)\), so this case is ruled out by the hypothesis.

There is an efficient algorithm to find \(\theta\), if it exists; because the above proof only requires calculating valuations which entails division operations in the ring. □

Before the algorithm let us illustrate the process on Example 6.

Example 7. Consider the polynomial \(f\) from Example 6. We want to find factors of \(f \equiv x^4 + 18x^3 + 33x^2 + 54x + 9\) mod 81. Fix \(\varphi := x \in \mathbb{Z}[x]\) and \(a = 2\).

Let us apply the reduction theorem (Theorem 11): \((\varphi^a - py)\) is a factor of \(f\) mod \(p^4\) iff
\[
E := f \cdot (\varphi^{3a} + \varphi^{2a}(py) + \varphi^a(py)^2 + (py)^3) \equiv 0 \mod (p^4, \varphi^{4a}).
\]

Putting the values \(\varphi = x, p = 3, a = 2\) and substituting \(y = y_0 + 3y_1\) [Lemma 12] we have,
\[
(x^4 + 18x^3 + 33x^2 + 54x + 9[x^6 + x^4(y_0 + 3y_1) + x^2(9y_0 + 3y_1)^2 + 27(y_0 + 3y_1)^3] \equiv 0 \mod (81, x^6).
\]
\[
\Leftrightarrow 9x^4[(6x^2 y_0 + 6x^2)y_1 + (3y_3^2 + y_0^2(x^2 + 6) + y_0(6x^2 + 2x^2 + 3) + 6x^2 + 3x^2)] \equiv 0 \mod (81, x^8).
\]

Using Claim 8,
\[
\Leftrightarrow (6x^2 y_0 + 6x^2)y_1 + 3y_3^2 + y_0^2(x^2 + 6) + y_0(6x^2 + 2x^2 + 3) + 6x^2 + 3x^2 \equiv 0 \mod (9, x^4). \quad (5)
\]
Reducing the last equation mod \((3, x^4)\) we have,
\[
x^2 y_0^2 + (2x^2) y_0 + x^2 \equiv 0 \mod (3, x^4).
\]
\[ y_0^2 + 2y_0 + 1 \equiv 0 \mod (3, x^2). \]

Notice that this is the same equation as for the case of \( k = 3 \) in Example 6.

Applying Panayi (1995); Berthomieu et al. (2013) (Theorem 10) on last equation, we get exactly one representative root \( y_0 = 2 + x \).

We substitute \( y_0 \rightarrow 2 + xy_0 \) in Equation (5) and simplify to get,

\[(2xy_0)y_0 + xy_0^3 + 2y_0^2 + (2x)y_0 \equiv 0 \mod (3, x^2). \tag{6}\]

Equation (6) gives us \( E_1(y_0) = xy_0^3 + 2y_0^2 + (2x)y_0 \mod (3, x^2) \) and \( E_2(y_0) = 2xy_0 \mod (3, x^2) \).

We want the values of \( y_0 \)'s, such that, \( \text{val}_x(E_1(y_0)) \) is at least \( \text{val}_x(E_2(y_0)) \). Since \( \text{val}_x(E_2(y_0)) \) is 1, we are forced to have \( y_0 = 0 \mod (3, x) \). In that case, Equation (6) is identically zero, so \( y_1 \) is free to take any value \( \mod (3, x^2) \).

Taking \( y_1 = 0 \) and \( y_0 = 2 + 0 \) we have the corresponding factor \( (x^2 - 3(2 + 0)) \equiv x^2 \mod 81 \). The co-factor of this is \( (x^2 + 18x + 39) \), giving

\[ f \equiv x^4 + 18x^3 + 33x^2 + 54x + 9 \equiv (x^2 + 75)(x^2 + 18x + 39) \mod 81. \]

### 4.4. Algorithm to find roots of \( E(y) \)

We have all the ingredients to give the algorithm for finding roots of \( E(y) \) modulo ideal \( \langle p^4, \varphi^{4a} \rangle \) of \( \mathbb{Z}[x] \).

**Input:** A polynomial \( E \in \mathbb{R}[y] \) defined as \( E := f \cdot (\varphi^{3a} + \varphi^{2a}(py) + \varphi^a(py)^2 + (py)^3) \).

**Output:** A set \( Z \subseteq R_0 \) and a bad set \( Z' \subseteq R_0 \), such that for each \( y_0 \in Z \), \( Z' \), there are (efficiently computable) \( y_1 \in R_0 \) (Theorem 17) satisfying \( E(y_0 + py_1) \equiv 0 \mod (p^4, \varphi^{4a}) \). These are exactly the roots of \( E \).

Also, both sets \( Z \) and \( Z' \) can be described by \( O(a) \) many representatives (Theorem 17). (Recall that \( a \leq d \)). Hence, a \( y_0 \in Z \) \( \iff \) can be picked efficiently.

We prove the correctness of Algorithm 2 in the following theorem.

**Theorem 17.** The output of Algorithm 2 (the set \( Z \) \( \iff \) \( Z' \)) contains exactly those \( y_0 \in R_0 \) for which there exist some \( y_1 \in R_0 \), such that, \( y = y_0 + py_1 \) is a root of \( E \) in \( R \). We can compute the set of \( y_1 \) corresponding to a given \( y_0 \in Z \) \( \iff \) \( Z' \) in \( \text{poly}(\deg f, \log p) \) time.

Thus, we efficiently describe (and exactly count) the roots \( y = y_0 + py_1 + p^2y_2 \) in \( R \) of \( E \), where \( y_0, y_1 \in R_0 \) are as above and \( y_2 \) can assume any value from \( R \).

**Proof.** The algorithm intends to output roots \( y \) of equation \( E \equiv f \cdot (\varphi^{3a} + \varphi^{2a}(py) + \varphi^a(py)^2 + (py)^3) \equiv 0 \mod (p^4, \varphi^{4a}) \), where \( y = y_0 + py_1 + p^2y_2 \) with \( y_0, y_1 \in R_0 \) and \( y_2 \in R \). From Lemma 12, any value of \( y_2 \) in \( \mathbb{F}_p \) makes \( y \) a root, and we encode this by substituting the symbol \( * \) for \( y_2 \).

Using Lemma 14, Algorithm 2 partially fixes \( y_0 \) from the set \( S_0 \) and reduces the problem to finding roots of an \( E'(y_0, y_1) \mod (p, \varphi^{4a}) \). In other words, if we can find all roots \( (y_0, y_1) \) of \( E'(y_0, y_1) \mod (p, \varphi^{4a}) \), then we can find (and count) all roots of \( E(y) \mod (p^4, \varphi^{4a}) \). This is accomplished by Step 1. From Lemma 14, \( |S_0| \leq 2 \), so loop at Step 3 runs only for a constant number of times.

Using Lemma 14, \( E'(y_0, y_1) \equiv E_1(y_0) + E_2(y_0)y_1 \mod (p, \varphi^{4a}) \) for a cubic polynomial \( E_1 \in R_0[y_0] \) and a linear polynomial \( E_2 \in R_0[y_0] \).

We find all solutions of \( E'(y_0, y_1) \) by going over all possible valuations of \( E_2(y_0) \) with respect to \( \varphi \). The case of valuation 0 is handled in Step 5 and valuation 4a is handled in Step 12. For the remaining valuations \( r \in [4a - 1] \), Lemma 15 shows that it is enough to find \( (z_0, z_1) \in R_0 \times R_0 \) such that \( \varphi^r|E_1(z_0) \) and \( \varphi^r||E_2(z_0) \).
Algorithm 2 Finding all roots of $E(y)$ in $R$.

1. Given $E(y_0 + py_1)$, using Lemma 14, get the set $S_0$ of all representative pairs $(a_0, i_0)$, where $a_0 \in R_0$ and $i_0 \in \mathbb{N}$, such that $p^4E(a_0 + \psi^{i_0}y_0 + py_1) \equiv (p^4, \psi^{4a_0})$.

2. Initialize sets $Z = \{\}$ and $Z' = \{\}$; seen as subsets of $R_0$.

3. for each $(a_0, i_0) \in S_0$ do

   4. Substitute $y_0 \mapsto a_0 + \psi^{i_0}y_0$, let $E'(y_0, y_1) = E_1(y_0) + E_2(y_0)\psi^1$ mod $(p, \psi^{4a_0})$ be the polynomial obtained from Lemma 14.

5. if $E_2(y_0) \not\equiv 0 \bmod (p, \psi)$ then find (at most one) $\theta \in R_0/(\psi)$ such that $E_2(\theta) \equiv 0 \bmod (p, \psi)$. Update $Z \leftarrow Z \cup (a_0 + \psi^{i_0} + \theta)$ and $Z' \leftarrow Z' \cup (a_0 + \psi^{i_0}(\theta + \psi^2))$.

6. for each possible valuation $r \in \{4a\}$ do

   7. Initialize sets $Z_r = \{\}$ and $Z'_r = \{\}$.

   8. Call Root-Find($E_1, \psi^r$) to get a set $S_1$ of representative pairs $(a_1, i_1)$ where $a_1 \in R_0$ and $i_1 \in \mathbb{N}$ such that $E_1(a_1 + \psi^{i_1}y_0) \equiv 0 \bmod (p, \psi^r)$.

   9. for each $(a_1, i_1) \in S_1$ do

      10. Analogously consider $E'_2(y_0) := E_2(a_1 + \psi^{i_1}y_0) \bmod (p, \psi^{4a_0})$.

      11. Call Root-Find($E_2, \psi^r$) to get a representative pair $(a_2, i_2)$ (if $E'_2$ is linear), where $a_2 \in R_0$ and $i_2 \in \mathbb{N}$ such that $E'_2(a_2 + \psi^{i_2}y_0) \equiv 0 \bmod (p, \psi^r)$.

      12. if $r = 4a$ then

         13. Update $Z_r \leftarrow Z_r \cup (a_1 + \psi^{i_1}(a_2 + \psi^{i_2} + \theta))$ and $Z'_r \leftarrow Z'_r \cup \{\}$. Else if $E'_2(a_2 + \psi^{i_2}y_0) \equiv 0 \bmod (p, \psi^{r+1})$ then

            15. Get a $\theta \in R_0/(\psi)$ (Lemma 16), if it exists, such that $E'_2(a_2 + \psi^{i_2}(\theta + \psi^0y_0)) \equiv 0 \bmod (p, \psi^{r+1})$. Update $Z'_r \leftarrow Z'_r \cup (a_1 + \psi^{i_1}(a_2 + \psi^{i_2}(\theta + \psi^2)))$.

         16. Update $Z_r \leftarrow Z_r \cup (a_1 + \psi^{i_1}(a_2 + \psi^{i_2} + \theta))$.

      17. end if

   18. end for

   19. Update $Z \leftarrow Z \cup (a_0 + \psi^{i_0}Z_r)$ and $Z' \leftarrow Z' \cup (a_0 + \psi^{i_0}Z'_r)$.

20. end for

21. end for

22. Return $Z$ and $Z'$.

Notice that the number of valuations is bounded by $4a = O(\deg f)$. At Step 6, the algorithm runs through the possible values of the valuation $r$ of $E_2(y_0) \in R_0[y_0]$ and subsequent computation finds all representative roots $b + \psi^{i_1} \bmod (p, \psi^r)$ (using Theorem 10), such that,

$$E_1(b + \psi^{i_1}y_0) \equiv E_2(b + \psi^{i_1}y_0) \equiv 0 \bmod (p, \psi^r).$$

The representative root $b + \psi^{i_1}$ is denoted by $(a_1 + \psi^{i_1}(a_2 + \psi^{i_2} + \theta))$ in Steps 13 and 16 of Algorithm 2.

Finally, we need to filter out those $y_0$’s for which $E_2(b + \psi^{i_1}y_0) \equiv 0 \bmod (p, \psi^{r+1})$. This can be done efficiently using Lemma 16, where we get a unique $\theta \in R_0/(\psi)$ for which,

$$E_2(b + \psi^{i_1}(\theta + \psi^0y_0)) \equiv 0 \bmod (p, \psi^{r+1}).$$

We store partial roots in two sets $Z_r$ and $Z'_r$, where $Z_r$ contains the bad values filtered out by Lemma 16 as $b + \psi^{i_1}(\theta + \psi^0y)$ and $Z_r$ contains all possible roots $b + \psi^{i_1}$. So, the set $Z_r - Z'_r$ contains exactly those elements $z_0$ for which there exists $z_1 \in R_0$ such that the pair $(z_0, z_1)$ is a root of $E'(y_0, y_1) \bmod (p, \psi^{4a_0})$.

Note that size of each set $S_1$ obtained at Step 9 is bounded by three using Theorem 10 ($E_1$ is at most a cubic in $y_0$). Again using Theorem 10, we get at most one pair $(a_2, i_2)$ at Step 11 for some $a_2 \in R_0$ and $i_2 \in \mathbb{N}$ ($E_2$ is linear in $y_0$).

Now, for a fixed $z_0 \in Z_r - Z'_r$ we can calculate all $z_1$’s by the equation

$$z_1 = z_1 := -(C(y_0)/L(y_0)) \bmod (p, \psi^{4a_0}).$$

Here $C(y_0) := E_1(z_0)/\psi^r \bmod (p, \psi^{4a_0})$ and $L(y_0) := E_2(z_0)/\psi^r \bmod (p, \psi^{4a_0})$. So, $z_1 \in R_0$ comes from the set $z_1 \in z_1 + \psi^{4a_0} \bmod (p, \psi^{4a_0})$. This can be done in $\text{poly}(\deg f, \log p)$ time.

Finally, the sets $Z = a_0 + \psi^{i_0}Z_r$ and $Z' = a_0 + \psi^{i_0}Z'_r$, for $(a_0, i_0) \in S_0$ and corresponding valid $r \in \{0, \ldots, 4a - 1\}$, returned by Algorithm 2, describe the $y_0$ for the roots of $E(y_0 + py_1) \bmod (p^4, \psi^{4a_0})$. The number of representatives in each of these sets is $O(a)$, since $|S_0| \leq 2$ and sizes of $Z_r$ and $Z'_r$ are only constant.
Since we can efficiently describe these \( y_0 \)'s and corresponding \( y_1 \)'s, and we know their precision, we can count all roots \( y = y_0 + py_1 + p^2 y_2 + R \) of \( E(y) \mod \langle p^4, \varphi^{4a} \rangle \).

4.5. Wrapping up Theorems 1 and 2

**Proof of Theorem 1.** We prove that given an arbitrary univariate \( f \in \mathbb{Z}[x] \) and a prime \( p \), a non-trivial factor of \( f \) modulo \( p^4 \) can be obtained in randomized \( \text{poly}(\deg f, \log p) \) time (or the irreducibility of \( f \) mod \( p^4 \) gets certified).

If \( f = f_1 f_2 \mod p \), where \( f_1, f_2 \) are two polynomials coprime in \( \mathbb{F}_p \), then we can efficiently lift this factorization to the ring \((\mathbb{Z}/(p^4))[x]\), using Hensel lemma (Lemma 4), to get non-trivial factors of \( f \) mod \( p^4 \).

For the remaining case, \( f = \varphi^e \mod p \) for an irreducible polynomial \( \varphi(x) \) modulo \( p \). The question of factoring \( f \) mod \( p^4 \) then reduces to root finding of a polynomial \( E(y) \mod \langle p^4, \varphi^{4a} \rangle \) by Reduction theorem (Theorem 11). Using Theorem 17, we get all such roots and hence a non-trivial factor of \( f \) mod \( p^4 \) is found. If there are no roots \( y \in R \) of \( E \), for all \( a \leq e/2 \), then the polynomial \( f \) is irreducible (by symmetry, if there is a factor for \( a > e/2 \) then there is a factor for \( a \leq e/2 \)).

**Proof of Theorem 2.** We are given a univariate \( f \in \mathbb{Z}[x] \) of degree \( d \) and a prime \( p \), such that, \( f \) mod \( p \) is a power of an irreducible polynomial \( \varphi(x) \). So, \( f \) is of the form \( \varphi(x)^e + ph(x) \mod p^4 \), for an integer \( e \in \mathbb{N} \) and a polynomial \( h \in (\mathbb{Z}/(p^4))[x] \) of degree \( \leq d \) (also, \( \deg \varphi^e \leq d \)). By unique factorization over the ring \( \mathbb{F}_p \), if \( \tilde{g} \) is a factor of \( f \) mod \( p \), then, \( \tilde{g} \equiv \tilde{v} \varphi^a \mod p \) for a unit \( \tilde{v} \in \mathbb{F}_p \).

First, we show that it is enough to find all the lifts of \( \tilde{g} \), such that, \( \tilde{g} \equiv \varphi^a \mod p \) for an \( a \leq e \). If \( \tilde{g} \equiv \tilde{v} \varphi^a \mod p \), then any lift has the form \( g(x) \equiv v(x) \varphi^a - py \mod p^4 \) for a unit \( v(x) \) in \((\tilde{v} + p^e) \subseteq (\mathbb{Z}/(p^4))[x] \). Any such \( g(x) \) maps uniquely to a \( g_1(x) := \tilde{v}^{-1} g(x) \mod p^4 \), which is a lift of \( \varphi^a \mod p \). So, it is enough to find all the lifts of \( \varphi^a \mod p \).

We know that any lift \( g \in (\mathbb{Z}/(p^4))[x] \) of \( \tilde{g}(x) \), which is a factor of \( f \), must be of the form \( \varphi^a - py \mod p^4 \) for a polynomial \( y \in (\mathbb{Z}/(p^4))[x] \). By Reduction theorem (Theorem 11), we know that finding such a factor is equivalent to solving for \( y \) in the equation \( E(y) \equiv 0 \mod \langle p^4, \varphi^{4a} \rangle \). By Theorem 17, we can find all such roots \( y \) in randomized \( \text{poly}(d, \log p) \) time, for \( a \leq e/2 \).

If \( a > e/2 \) then we replace \( a \) by \( b := e - a \), as \( b \leq e/2 \), and solve the equation \( E(y) \equiv 0 \mod \langle p^4, \varphi^{4b} \rangle \) using Theorem 17. This time the factor corresponding to \( y \) will be, \( g \equiv f / \varphi^b - py \equiv E(y) / \varphi^{4b} \mod p^4 \), using Reduction theorem (Theorem 11).

The number of lifts of \( \tilde{g}(x) \) which divide \( f \) mod \( p^4 \) is the count of \( y \)'s that appear above. This is efficiently computable via Algorithm 2.

5. Barriers to extension modulo higher powers \( p^k \)

The reader may wonder about polynomial factoring when \( k \) is greater than 4. In this section we will discuss the issues in applying our techniques to factor \( f(x) \mod p^5 \).

Given \( f = \varphi^e \mod p \), finding one of its factor \( \varphi^a - py \mod p^5 \), for \( a \leq e/2 \) and \( y \in (\mathbb{Z}/(p^5))[x] \), is reduced to solving the equation

\[
E := f \cdot (\varphi^{4a} + \varphi^{3a} (py) + \varphi^{2a} (py)^2 + \varphi^{a} (py)^3 + (py)^4) \equiv 0 \mod \langle p^5, \varphi^{5a} \rangle
\]

By Lemma 12, the roots of \( E \) mod \( \langle p^5, \varphi^{5a} \rangle \) are of the form \( y = y_0 + py_1 + p^2 y_2 + p^3 y_3 \) in \( R \), where \( y_0, y_1, y_2 \in R_0 \) need to be found.

**First issue.** The first hurdle comes when we try to reduce root-finding modulo the bi-generated ideal \( \langle p^5, \varphi^{5a} \rangle \subseteq \mathbb{Z}[x] \) to root-finding modulo the principal ideal \( \langle \varphi^{5a} \rangle \subseteq \mathbb{F}_p \). In the case \( k = 4 \), Lemma 14 guarantees that we need to solve at most two related equations of the form \( E'(y_0, y_1) \equiv 0 \mod \langle p^4, \varphi^{4a} \rangle \) to find exactly the roots of \( E \) mod \( \langle p^4, \varphi^{4a} \rangle \). Below, for \( k = 5 \), we show that we have exponentially many candidates for \( E'(y_0, y_1, y_2) \in R_0 \) and it is not clear if there is any compact efficient representation for them.

Putting \( y = y_0 + py_1 + p^2 y_2 \) in Eqn. (7) we get,

\[
E(y) := E_1(y_0) + E_2(y_0) y_1 + E_3(y_0) y_2 + (f \varphi^{2a} p^4 y_1^2) \equiv 0 \mod \langle p^5, \varphi^{5a} \rangle.
\]
where \( E_1(y_0) := f_0 + f_1 y_0 + f_2 y_0^2 + f_3 y_0^3 + f_4 y_0^4 \) is a quartic in \( R[y_0] \), \( E_2(y_0) := f_0 y_0^2 + f_1 y_0^3 + f_2 y_0^4 \) is a quadratic in \( R[y_0] \) and \( E_3(y_0) := f_0 y_0^3 + f_1 x y_0^4 \) is linear in \( R[y_0] \).

To divide Eqn. (8) by \( p^3 \), we go \( \mod (p^3, \varphi_{5a}) \) obtaining

\[
E(y) \equiv E_1(y_0) \equiv f_0 + f_1 y_0 + f_2 y_0^2 + f_3 y_0^3 \mod (p^3, \varphi_{5a}),
\]

a univariate quadratic equation which requires the whole machinery used in the case \( k = 3 \). We get this simplified equation since \( E_3(y_0) \equiv 0 \mod (p^4, \varphi_{5a}) \) and \( E_2(y_0) \equiv f_0 y_0^2 \equiv \varphi_{5a}^2 y_0^2 \equiv 0 \mod (p^4, \varphi_{5a}) \).

But, to really reduce Eqn. (8) to a system modulo the principal ideal \( \langle \varphi_{5a} \rangle \subseteq \mathbb{F}_p[x] \), we need to divide it by \( p^4 \). So, we go \( \mod (p^4, \varphi_{5a}) \):

\[
E(y) \equiv E_1'(y_0) + E_2'(y_0) y_1 \equiv 0 \mod (p^4, \varphi_{5a})
\]

where \( E_1'(y_0) \equiv E_1(y_0) \mod (p^4, \varphi_{5a}) \) is a cubic in \( R[y_0] \) and \( E_2'(y_0) \equiv E_2(y_0) \mod \langle p^4, \varphi_{5a} \rangle \) is linear in \( R[y_0] \). This requires us to solve a special bivariate equation which requires the machinery used in the case \( k = 4 \).

Now, the problem reduces to computing a solution pair \( (y_0, y_1) \in (R_0)^2 \) of this bivariate equation. We can apply the idea used in Algorithm 2 to get all valid \( y_0 \) efficiently, but since \( y_1 \) is a function of \( y_0 \), we need to compute exponentially many \( y_1 \)'s. So, there seem to be exponentially many candidates for \( E'(y_0, y_1, y_2) \), that behaves like \( E(y)/p^4 \) and lives in \( \mathbb{F}_p[x]/(\varphi_{5a})[y_0, y_1, y_2] \). At this point, we are forced to compute all these \( E \)'s, as we do not know which one will lead us to a solution of Eqn. (8).

**Second issue.** Even if we resolve the first issue and get a valid \( E' \), we are left with a trivariate equation to be solved \( \mod (p, \varphi_{5a}) \) (Eqn. (8) after shifting \( y_0 \) and \( y_1 \) then dividing by \( p^4 \)). We could do this when \( k = 4 \), because we could easily write \( y_1 \) as a function of \( y_0 \). Though, it is unclear how to solve this trivariate equation now as it is nonlinear in both \( y_0 \) and \( y_1 \).

For \( k > 5 \) the difficulty will only increase because of the recursive nature of Eqn. (7) with more and more unknowns (with higher degrees).

### 6. Conclusion

The study of von zur Gathen and Hartlieb (1998, 1996) sheds some light on the behavior of the factoring problem for integral polynomials modulo prime powers. It shows that for “large” \( k \) the problem is similar to the factorization over \( p \)-adic fields (already solved efficiently by Cantor and Gordon (2000)). But, for “small” \( k \) the problem seems hard to solve in polynomial time. We do not even know a practical algorithm.

This motivated us to study the case of constant \( k \), with the hope that this will help us invent new tools. In this direction, we made significant progress by giving a unified method to factor \( f \mod p^k \) for \( k \leq 4 \). We also refined Hensel lifting for \( k = 4 \), by giving all possible lifts of a factor of \( f \mod p \), in the classically hard case of \( f \mod p \) being a power of an irreducible.

We gave a general framework (for any \( k \)) to work on, by reducing factoring in a big ring to root-finding in a smaller ring. We leave it open whether we can factor \( f \mod p^2 \), and beyond, within this framework.

We also leave it open, to efficiently get all the solutions of a bivariate equation, in \( \mathbb{Z}/(p^k) \) or \( \mathbb{F}_p[x]/(\varphi_k) \), in a compact representation. Surprisingly, we know how to achieve this for univariate polynomials (Panayi, 1995; Berthomieu et al., 2013). This, combined with our work, will probably give factoring \( \mod p^k \), for any \( k \).
