

Resource Sharing for GPUs

Vishwesh Jatala (IITK), Jayvant Anantpur (IISc), Amey Karkare (IITK)

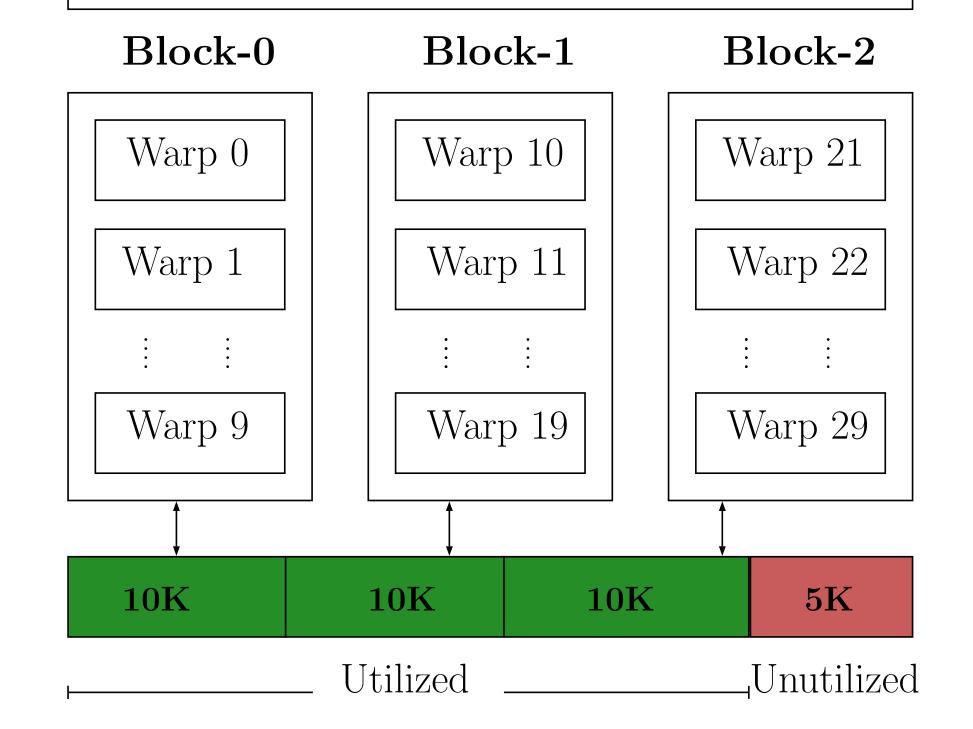

Problem

Resource allocation at thread block granularity in Graphics Processing Units (GPUs) has the following disadvantages [1]:

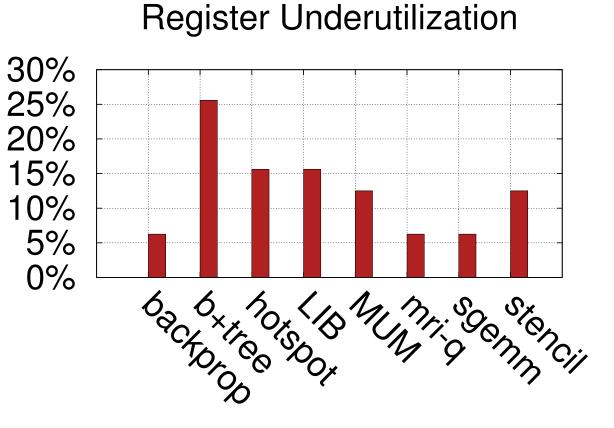

- 1. Resource underutilization
 - Registers and Scratchpad Memory get underutilized
- 2. Reduction in thread level parallelism (TLP)

Motivating Example

Number of resources per SM: 35K Units Resource requirment per block: 10K Units Thread block size: 10 Warps

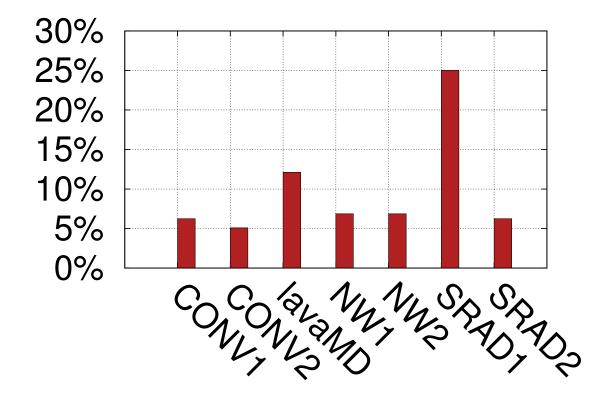

Resource Underutilization

Scratchpad Underutilization

- Limited number of resident threads and blocks in streaming multiprocessors (SMs)
- 3. Potential reduction in throughput

Solution: Resource Sharing

Idea: Share the resources between thread blocks

Strategy:

- Increase the TLP by launching additional thread blocks in each SM
- Minimize the resource wastage with the help of addition thread blocks that:
 - 1. Use wasted resource

Example (Resource Sharing)

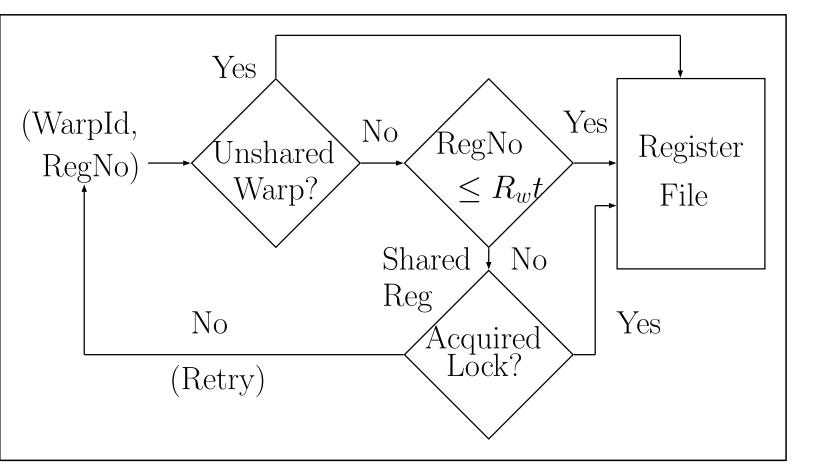

Number of resources per SM: 35K Units Resource requirment per block: 10K Units Thread block size: 10 Warps **Resource Sharing:** 50%

$\begin{array}{c} \textbf{Block-0} \\ (\textbf{Unshared}) \end{array}$	$\begin{array}{c} \textbf{Block-1}\\ (\textbf{Unshared}) \end{array}$	$\begin{array}{c} \textbf{Block-2} \\ \textbf{(Shared)} \end{array}$	Block-3 (Shared)
Warp 0	Warp 10	Warp 21	Warp 31
Warp 1	Warp 11	Warp 22	Warp 32
			: :

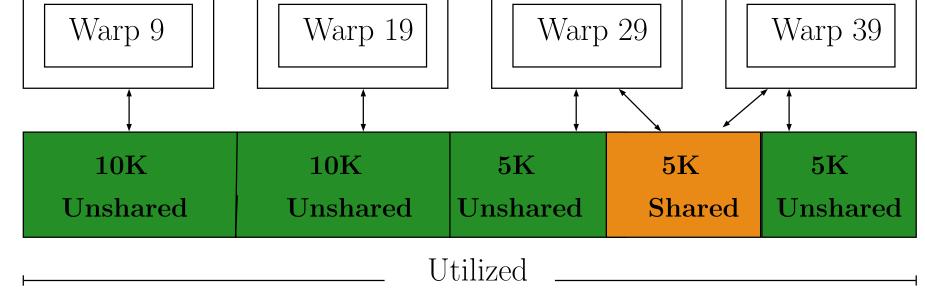

Resource Access Mechanism

A shared warp can access unshared register directly, but it can access shared register only after acquiring an exclusive lock.

 R_w : Number of registers required for a warp t: Threshold, used for computing %ge of resource sharing

- 2. Share the resources with other resident blocks
- Access resources effectively to avoid deadlocks and to guarantee minimum number of blocks that always make progress.

Note: In register sharing, pair of warps, one from each shared block, share their registers appropriately.

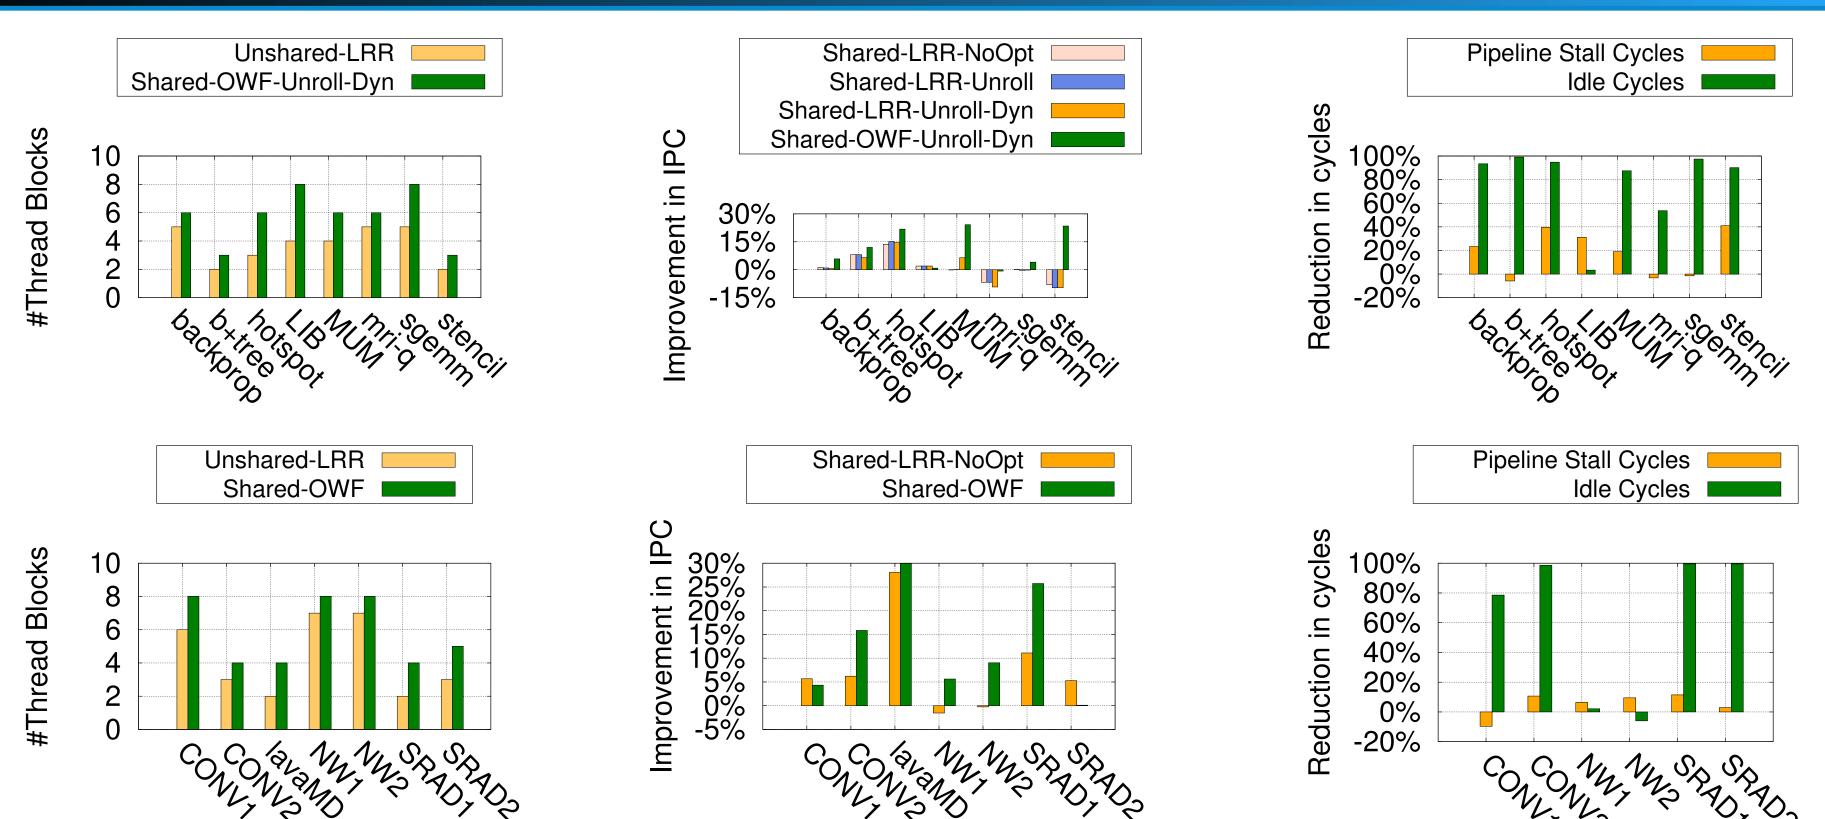

Note: The scratchpad access mechanism is implemented in the similar way The details of our approach are discussed in [3].

Optimizations

Type of warps in the SM:

- Unshared warps (warps from unshared thread block)
- Owner warps (warps that have exclusive lock)
- Non-owner warps (warps without lock)
- 1. Owner Warp First (OWF):

Results

- Schedule the warps according to the priority: owner warp, unshared warp, and non-owner warp
- 2. Unroll Register Declarations:
 - Unroll and re-order register declarations to delay access to shared registers
- 3. Dynamic Warp Execution (Dyn):
 - Control the execution of long latency instructions from non-owner warps to reduce cache misses.

Increase in TLP **Reduction in idle and stall cycles** Improvement in IPC **Note:** First row of the results corresponds to register sharing, second row corresponds to scratchpad sharing

Experimental Setup

Resource	GPU Configuration [2]	
No of SMs	14	
Max Num of TBs	8	
Max Num of Threads	1536	
Number of Registers	32768	
Scratchpad Memory	$16 \mathrm{KB}$	
Warp Scheduling	LRR
